Symptoms in Infancy—Polyuria is never present at birth Its subsequent occurrence, however, can be readily predicted by parents acquainted with the disease, as in the instances described by Weil in which the parents were able to tell by the sixth month whether or not the infant would be a "drinker" The important signs are 1 Dissatisfaction with breast milk 2 Marked restlessness McIlraith records two instances of peculiar "infantile fits" 3 Nocturnal wakefulness relieved only after drinking water (Gee, Pain, McIlraith) Liebmann emphasizes the frequency of diarrhea

Symptoms in Childhood and Adult Life—At about 2 years of age, paralleling the transference of the function of regulation of water exchange from the skin

and gastro-intestinal tract to the kidneys, the symptoms associated with the syndrome of diabetes insipidus appear Thus there are nocturnal and diurnal polyuria, polydipsia, often pollakiuria, and enuresis, the latter at first diurnal and nocturnal, and subsequently nocturnal only Enuresis may persist even to adult life According to Weil, the symptoms of hereditary diabetes insipidus are maximum in extent between the ages of 20 and 30, diminishing after 50 The thirst is sometimes unusually marked, the patient drinking as much as a liter of water an hour Pain² noted the occurrence of death after an excessive drinking bout Adolescence and commencement of sexual relationships often advantageously affect the symptoms

It is of interest to note that Fitcher observed a diminution of libido in patients with diabetes insipidus Although excessive thirst and polyuria may be the sole symptoms, the patients frequently complain of dryness of the mouth, a thick tenacious sputum which is difficult to bring up, coldness of the hands and feet, pains in the joints, a sense of pressure in the head, hot flushes, a prickly sensation of the skin, and constipation The appetite is fairly good as a rule, large quantities of fluid being taken with the meals to moisten the food Objectively, the patients sometimes have a high forehead, a marked temperature lability, and a tendency to bradycardia The skin is dry and coarse, and there is very little perspiration even after vigorous exercise One of Knopfmacher's patients had congenital ichthyosis In addition, there may be a marked distention of the bladder Ehrmann² and McIlraith² note that the children are occasionally backward Imbeciles are also described Roentgenograms of the skull and the region of the sella turcica show no abnormalities (Chase²) In one of our cases (case 3), exaggeration of the digital markings of the skull was present

During febrile bouts the polyuria and polydipsia may completely disappear, only to return after convalescence During the course of pregnancy there is an aggravation of the symptoms, with a reversion to the former level after parturition Patients with hereditary diabetes insipidus are not more than usually prone to intercurrent illnesses³

Chemical studies are reported in a few instances of hereditary diabetes insipidus In our cases the observations are in general within normal limits Gibson, Magers and Dulaney,⁹ using the same technic, secured sugar tolerance curves resembling those of diabetes mellitus in six patients with diabetes insipidus

Under normal circumstances the urinary output varies with the sodium chloride output In diabetes insipidus, according to Lichtwitz,¹⁰ there is a complete dissociation of sodium chloride and water output

THERAPY

Because of the occurrence of symptoms in early childhood and their persistence throughout adult life, patients with diabetes insipidus become so accustomed to the associated discomforts and inconveniences, which they have accepted as their lot, that they often do not seek relief Patient 1 insisted that quenching her thirst was her greatest delight in life and only agreed to submit to our investigation provided we did not limit her water intake As emphasized by Snell and Rowntree¹¹ and

by Weir, Larson and Rowntree,¹² water intoxication may occur, subsequent to restriction of the fluid intake. It is interesting to note that when fluids were withheld for a period of three hours in conjunction with laboratory studies in our patient, restlessness, irritability, hot flushes and headache appeared. After one such "water fast" of three hours, A. M. drank 2 liters of water within a period of half an hour.

According to Veil, a restriction of protein and salt in the diet diminishes the thirst and polyuria. Reith² reported improvement in the clinical picture with large doses of valerian. Improvement followed lumbar puncture in one instance.¹³ Cold baths sometimes relieve the thirst.

Since von den Velden¹⁴ used an extract of the pituitary gland in the treatment of diabetes insipidus in 1913, various posterior lobe derivatives have proved effective in this condition. An exception is the frequent failure of treatment with solution of pituitary in post-encephalitic diabetes insipidus (Snell and Rowntree). In Turner's¹⁵ case, a child, aged 6, treatment with solution of pituitary was effective only after the fluid intake was diminished. Weir, Larson and Rowntree¹² emphasize the possibility of water retention subsequent to pituitary therapy with symptoms of water intoxication. Chase and Mettel¹⁶ report a gain in weight following treatment with solution of pituitary. This was not present in our cases.

Solution of pituitary by intranasal spray, once the difficulties in technic have been overcome, yields excellent results and avoids the discomfort of repeated hypodermic injections. This method was first used by Blumgart¹⁷ in 1922. The results are sometimes better than with the subcutaneous method of administration. This, as Blumgart mentions, is probably due to the rapid absorption of the solution of pituitary in virtue of the direct communication of the lymphatics of the nasal mucosa with the subarachnoid space. At no time has there been any irritation of the nasal mucosa or any other untoward symptom resulting from the treatment with solution of pituitary. The doses of solution of pituitary, effective at the time the therapy was instituted, are just as effective after a period of five months.

PROGNOSIS

The prognosis in hereditary diabetes insipidus after infancy, as evidenced by the reports of Weil, is excellent. It is not uncommon for these patients to live to the seventh, eighth and ninth decades.

CONCLUSIONS

1 Several members of a family with hereditary diabetes insipidus were studied.

2 In the two available members, solution of pituitary, administered by hypodermic injection and nasal spray, greatly lowered the level of water exchange and completely controlled the diabetes insipidus syndrome.

CHOLECYSTOGRAPHY ITS CLINICAL EVALUATION

A STUDY OF 2,070 CASES

ARTHUR N. FERGUSON, M.D.

AND

WALTER L. PALMER, M.D.

CHICAGO

The present article is a review of our experience with intravenous cholecystography in the diagnosis of gallbladder disease in 2,070 patients over a period of five years. In the numerous articles on cholecystography which have appeared, the test seems to have been carried out chiefly on patients with symptoms of gallbladder disease. Consequently, the statistics given do not indicate the reliability of the method *per se* but rather the reliability of the method when used in conjunction with a clinical diagnosis of gallbladder disease. In our clinic, the dye has been given in a somewhat routine fashion to a wide variety of patients, although the majority of them have been referred to the gastrointestinal service because of some type of abdominal distress. Tetiothalein sodium-N N R or, in a small group, phenetiothalein sodium-N N R, has been used, the technic being that first suggested by Case,¹ in which the dye is given late in the afternoon, followed by a small fat-free meal. No more food or liquid is then taken into the stomach until after films have been made the following morning. Two exposures are taken at about a thirty minute interval, a fatty meal is then given and a third film made thirty minutes later.

TABLE 1—Three Groups of Visualization

Group		Number	Per Cent
1	Good visualization with no evidence of stone	1,398	67.6
2	Stones demonstrated regardless of the type of visualization	192	9.2
3	Faint visualization and nonvisualization with no evidence of stone	480	23.2
Total		2,070	100

For the purpose of analysis, the cholecystographic diagnoses have been arbitrarily divided into three groups, as shown in table 1.

Approximately two thirds (1,398) of the cases fall into the first group, that of good visualization of the gallbladder without stone. The corresponding clinical diagnoses are given in table 2.

In only thirty-five of these is there a history suggestive of biliary disease. This small group deserves especial consideration. The symptoms are very suggestive of gallbladder disease but the gallbladder visualization is normal. In seven of these, cholecystectomy has been performed. A careful pathologic and clinical analysis of these seven cases has revealed that fairly definite pathologic evidence of cholecystitis is present in only one, whereas in six the gallbladder seems normal both grossly and microscopically. It must be admitted that considerable difference of opinion exists as to what constitutes an anatomically normal gallbladder. We have taken the view that the presence of occasional collections of round cells in the wall are not abnormal, since they are found in prac-

¹ Case J. T. Evaluation of Cholecystography, J. A. M. A. 92: 291 (Jan. 26) 1929.

tically all gallbladders. On the other hand, marked leukocytic infiltration with or without an increase in connective tissue in the wall has been considered as definite evidence of cholecystitis. When judged in this manner, only one of the seven can be considered as

cholesterol stone. Reexamination would probably have demonstrated the stones in both instances. The second group consists of 192 cases in which stones have been demonstrated cholecystographically. Of these, 83 (43.2 per cent) are positive shadows indicating calcium containing stones, and 109 (56.8 per cent) are negative shadows of nonopaque stones in gallbladders with faint or good visualization. Fifty-seven of these cases have come to operation or autopsy, as shown in table 3. The diagnosis of stone on the basis of positive shadows has been correct in all of the thirty cases, an accuracy of 100 per cent. In all the twenty-eight instances of negative shadows interpreted as nonopaque stones, cholelithiasis has been found in twenty-seven, an accuracy of 96.4 per cent. In the one normal case, the x-ray report had been good visualization with doubtful nonopaque stone. This illustrates the difficulty encountered occasionally even by the experienced observer in differentiating between gas bubbles in the intestine and the negative shadows of nonopaque stones. The chief difficulties encountered by us have been in the third group of 480 cases (23.2 per cent of the total), comprising 310 instances of nonvisualization and 170 of faint visualization without evidence of stone. The diagnosis has been checked anatomically in 102 of

TABLE 2—Clinical Diagnoses in 1,398 Cases of Good Visualization of the Gallbladder with No Evidence of Stone

Disease	No of Cases	Disease	No of Cases

Hydronephrosis	2	Ventral hernia	4

definite cholecystitis. Clinically, it is noteworthy that only partial relief has been obtained in four cases and no relief whatever in two. One patient has not been traced. It seems probable, therefore, that the clinical diagnosis of cholecystic disease is in error in the great majority of the cases in this group and that the cholecystographic observations are correct.

It is, of course, entirely possible that asymptomatic cholelithiasis may have been present in a portion of these 1,398 cases, even though a good visualization of the gallbladder without evidence of stone was obtained. Shay² has reported such observations. At the present time, two mistakes of this type are known to have been made in our series. In one of these the report was that of good visualization, but the patient had breathed in all of the films so that the shadow was not clear. Later, she had an attack of acute gallbladder colic,

TABLE 3—Diagnosis at Operation in Cases in Which Stones Were Demonstrated by Cholecystography

Cholecystographic Diagnosis	Stones Found at Operation or Autopsy	No Stones at Operation	Accuracy, per Cent
Calcified stones (positive shadows)	30	0	100
Nonopaque stones (negative shadows)	27	1	96.4
Total	57	1	98.3

operation was done as an emergency measure, and a gangrenous gallbladder containing one large stone was found. In the second case, the report was that of good visualization with a questionable nonopaque stone. The patient presented no evident gallbladder symptoms at the time of examination but was later subjected to operation. The gallbladder was found to contain one

* Two of these diagnoses were confirmed at autopsy instead of at operation.
† Gallbladder was reported normal at operation but was not removed.

these with the results shown in table 4. It should be emphasized that the basis for operative intervention in this group has been the clinical diagnosis together with the cholecystographic observations, not the latter alone. Seven (58.3 per cent) of the twelve patients with a faint visualization were found to have cholecystic disease, whereas three (25.0 per cent) had definitely normal gallbladders. In this small group the accuracy of the clinical diagnosis plus the faint visualization was only 58.3 per cent with a definite error in 25.0 per cent. In the group, on the other hand, in which the diagnosis was based on the clinical evidence plus a nonvisualization of the gallbladder, eighty-one (90 per cent) of the ninety patients were found to have an abnormal gallbladder, three had some other type of intra-abdominal disease and six had no demonstrable lesion either in the gallbladder or elsewhere. In these six cases, three of which will be reported in detail, the gallbladder was removed and found to be normal microscopically. In this series, then, the accuracy of the clinical diagnosis of gallbladder disease, when coupled with a nonvisualization of the gallbladder, is 90 per cent with a definite error of 6.7 per cent, some other disease being present in three cases (3.3 per cent): carcinoma of the stomach, carcinoma of the pancreas, and tuberculous peritonitis.

2. Bockus, H. L., Shay, Harry, Willard, J. H., and Pessel, J. F. Comparison of Biliary Drainage and Cholecystography in Gallstone Diagnosis, J. A. M. A. 96: 311 (Jan. 31) 1931.

In the last instance, that of tuberculous peritonitis, the dye had been given on two separate occasions with a questionable faint visualization the first time and nonvisualization the second

There have been 124 cases of faint visualization and 119 of nonvisualization in which an anatomic check of the diagnoses has not been available and in which there has been no clinical evidence of disease of the biliary

TABLE 5—Results of Repetition of the Test in Nonoperative Cases of Faint Visualization of the Gallbladder with No Clinical Evidence of Disease of the Biliary Tract

Clinical Diagnosis	Results of Second Examination			Total
	Nonvisualization	Faint Visualization	Good Visualization With out Stone	
Bowel distress (colitis)			3	3
Duodenal ulcer			3	3
Gastric ulcer	1	—	—	1
Total	1 (14%)	—	6 (86%)	7 (100%)

tract, the various diagnoses being similar to those given in table 2. It seems reasonable to assume, however, that the accuracy of the diagnosis is not higher and probably is very much lower than that found in those cases in which operation was done because of the combined clinical and cholecystographic evidence, i. e., 58.3 per cent in the cases of faint visualization and 90 per cent in those of nonvisualization.

In thirty-one of these cases, the accuracy of the cholecystographic diagnosis has been tested by a repetition of the examination, the results being shown in tables 5 and 6. All of the cases of faint visualization included in table 6 have given a good visualization on the second examination except one, which has resulted in nonvisualization. If it is assumed that this one case is really one of cholecystitis and that the others represent normal gallbladders, the accuracy of a faint visualization in the diagnosis of cholecystic disease in this group is only 14 per cent, and the error 86 per cent.

TABLE 6—Results of Repetition of the Test in Nonoperative Cases of Nonvisualization of the Gallbladder with No Clinical Evidence of Disease of the Biliary Tract

Clinical Diagnosis	Results of Second Examination			Total
	Nonvisualization	Faint Visualization	Good Visualization With out Stone	
Arthritis of spine		1		1
Bowel distress (colitis)	2		1	3
Chronic cystitis	1			1
Duodenal ulcer	3	3	4	10
Gastric ulcer			1	1
Ilejunal ulcer			1	1
Nervous vomiting			1	1
No organic disease		1		1
Postoperative adhesions	1			1
Total	7 (29.2%)	4 (37.5%)	5 (33.3%)	24 (100%)

When the same criteria are used, the results of repetition of the test in the cases of nonvisualization of the gallbladder without clinical evidence of disease of the biliary tract shown in table 6 the accuracy of a nonvisualization alone is only 29.2 per cent, 37.5 per cent are doubtful, and 33.3 per cent are definitely incorrect.

REPORT OF CASES

In order to illustrate and emphasize the danger of relying entirely on the cholecystographic examination,

three of the cases mentioned are herewith presented in detail.

CASE 1—A single white woman, aged 23, admitted with the complaints of mild distress in both lower quadrants of the abdomen of three years' duration, and of constipation for two and one-half years, had had irregular attacks of pain localized to the right epigastrium associated with nausea and vomiting, for three months previous to admission. These had usually appeared a few minutes after eating, had been so severe that they caused her to double up and cry, and had lasted from a few minutes to several hours. The physical examination was essentially normal except for rather generalized abdominal tenderness. Routine analysis of the blood, urine, stool and gastric contents was negative. Cholecystographic examination, Dec. 2, 1929, was reported as nonvisualization with no evidence of stone. This was repeated, December 16, and again resulted in nonvisualization. The attending physician's note, December 18, reads as follows: "The clinical diagnosis involves a difficult differentiation between functional bowel distress and gallbladder disease. The distress is suggestive of cholecystitis although it is not localized to the gallbladder region. Two intravenous Graham-Cole tests have failed to visualize the gallbladder. On the basis of the above, I believe cholecystectomy is indicated but suspect that it will not give complete relief from the distress." A cholecystectomy was performed, December 26. The operative and pathologic reports state that the gallbladder was essentially normal. Ten days after discharge the patient was seen in the outpatient clinic and the following note appears on her chart: "Patient returns saying that she has the same pain as before the operation." Following the institution of a bland, low-residue, nonlaxative diet, the distress disappeared.

CASE 2—A married white man, aged 44, entered the clinic complaining of distress in the upper abdominal tract of fifteen years' duration, which bore the typical ulcer relationships to food taking. The roentgenologic examination revealed a frank duodenal ulcer and a nonvisualization of the gallbladder. Because the history was that of ulcer and not of cholecystic disease, he was placed on medical ulcer management, which he followed only fairly well after his discharge from the hospital. Nearly two years later his ulcer distress reappeared and he reentered the hospital. At this time he stated that, in addition to the ulcer distress, he had had two episodes of severe night pain. These attacks occurred after eating heavy midnight suppers, one six weeks and the other four weeks previous to admission. The distress was widespread across the epigastrium, radiated through to the back, was so severe that he was doubled up with pain, and kept him awake most of the night. For a week previous to admission there was considerable nausea and vomiting. Physical examination revealed tenderness in the epigastrium and right upper quadrant. Roentgenologic examination at this time showed a duodenal ulcer with high grade stenosis and again revealed nonvisualization of the gallbladder. At operation a few days later a stenotic ulcer was found but the gallbladder was so perfectly normal grossly that the surgeon was unwilling to remove it. Since the operation there has been no return of the distress.

CASE 3—A married white woman, aged 27, admitted to the clinic, complained of anorexia, frequent nausea, vomiting, distress in the upper abdominal tract immediately after eating and constipation requiring cathartics, all present for six years. Domestic difficulties had caused considerable emotional disturbance and had resulted in a separation from her husband six months previously. A short period of dietary treatment had resulted in no improvement. Attacks of abdominal pain had soon appeared located at first in the right lower quadrant, then in the left lower quadrant, in the epigastrium and occasionally in the right upper quadrant, variable in nature, but frequently so severe that opiates had been required. She was admitted to the hospital during an attack of pain in the right lower quadrant radiating into the right side of the vulva. Physical examination was essentially negative except for generalized abdominal tenderness, especially in the two lower quadrants, the right upper quadrant and the epigastrium. The temperature was normal, the white blood count was 11,600. Urinalysis was normal except for the finding of a few red blood cells.

Morphine was required to relieve the pain, and the following morning the attack was found to have subsided completely. Subsequent urologic examination failed to reveal any evidence of disease in the urinary tract.

Cholecystographic examination, when the patient was first seen, had revealed nonvisualization of the gallbladder. This was repeated two months later with the same result. In view of the complete absence of objective evidence of disease elsewhere, the patient was referred to surgery for cholecystectomy, although it was recognized that the clinical picture was not typically that of biliary disease. Examination of the gallbladder showed it to be normal both grossly and microscopically. The patient remained symptom free for about six weeks after her discharge from the hospital and then returned to the

TABLE 7—*Diagnostic Value of a History of Colic as Compared with Cholecystographic Data*

Diagnosis at Operation	History of Colic			Cholecystographic Observations				
	Present	Absent	Total	Stones Demonstrated	Visualization			Total
					None	Faint	Good	
Cholelithiasis	118 90.1%	13 9.9%	131 100%	53 42.0%	69 52.7%	5 3.8%	2* 1.5%	131 100%
Definite cholecystitis with out stone	7 77.8%	2 22.2%	9 100%		6 66.7%	2 22.2%	1 11.1%	9 100%

* Errors due to poor technic in one instance and incorrect interpretation in the other.

outpatient department, stating that the nausea, vomiting and mild abdominal distress had returned. Strict management of the intestinal distress was then instituted with only partial relief of the distress.

It seems to us necessary to conclude that in each of these three cases the gallbladder was normal even though it was not visualized in either of two examinations.

It has been implied in this paper that, aside from the actual demonstration of stone, cholecystographic evidence of cholecystic disease is of the greatest value when it confirms the clinical diagnosis. It thus becomes of interest to compare the frequency of biliary colic with that of positive cholecystographic evidence in cases in which operation reveals the presence of gallbladder disease. The results are shown in table 7.

When stones were present, colic was recorded in 90 per cent of the cases and positive cholecystographic evidence in 94.7 per cent.

COMMENT

The diagnostic value of cholecystography seems quite clear in certain respects. The percentage of accuracy is probably above 98 when a good visualization of the gallbladder is found and no stone shadows are seen. On the other hand, an apparently normal gallbladder occasionally shows a faint visualization or none at all. The actual demonstration of opaque or nonopaque stones is the most conclusive evidence of cholelithiasis.

The greatest difficulty has been encountered in evaluating faint visualization or nonvisualization of the gallbladder. From the clinical standpoint, it is advisable to consider seriously the cholecystographic report of a faint or a total absence of visualization of the gallbladder only if it corroborates the clinical history. This is illustrated by the following figures. When the diagnosis of gallbladder disease was based on a faint visualization together with the clinical history, it was found correct at operation in 58.3 per cent of the cases, when based on a faint visualization alone, it was probably correct in only 14 per cent of the cases. Similarly, when the diagnosis of cholecystic disease was made

from nonvisualization together with the clinical history, it was later proved anatomically to be correct in 90 per cent of the cases, whereas nonvisualization in the absence of clinical symptoms was proved by repetition of the test to be incorrect in at least 33.3 per cent of the instances.

In proved cases of cholelithiasis, a history of biliary colic was encountered with almost the same frequency as was cholecystographic evidence of gallbladder disease.

CONCLUSIONS

1 A good visualization of the gallbladder by cholecystography with no evidence of stones indicates a normal gallbladder in a very high percentage of the cases. Exact figures as to its accuracy are difficult to give.

2 The accuracy of diagnosis when stones are demonstrated as positive or negative shadows approaches 100 per cent.

3 The accuracy of a faint visualization, when combined with a clinical history suggestive of biliary disease, is 58.3 per cent, that of nonvisualization when combined with a positive clinical history, 90 per cent.

4 In the absence of a clinical history suggestive of gallbladder disease, the accuracy of a faint visualization is less than 14 per cent, that of nonvisualization, considerably less than 66.6 per cent.

5 In the cases in which cholecystic disease was found at operation, a history of colic was noted almost as frequently as was cholecystographic evidence of gallbladder disease.

SODIUM CARBONATE (MONOHYDRATED)
IN THE TREATMENT OF VERNAL
CONJUNCTIVITIS

LOUIS LEHRFELD, M.D.
PHILADELPHIA

I advocate the use of sodium carbonate in solution, 5 and 10 grains to the ounce of water (0.3 and 0.65 Gm. to 30 cc.), instilled three drops, four times daily, during the active stages of vernal conjunctivitis, both limbic and palpebral. As a supplement, the eye should be irrigated with cold boric acid solution by means of an eye cup, seven times daily.

Having proved that vernal conjunctivitis is an ocular manifestation of an allergy due principally to dusts and pollens, and having observed that desensitization by means of dusts and pollens does not always effect immediate relief, I¹ came to the conclusion that the avenue of approach in the treatment of this disease would be to render inert the exciting agents that enter the eye, or at least to remove them from the eye in such quantities as to minimize the degree of contact and thus keep the patient comparatively free from the clinical symptoms of this disease.

I have described on previous occasions the characteristic chewing gum mucus, which is seen in no other ocular disease. The patients invariably state that the itching, which is the most distressing symptom, is relieved after rubbing the eyes and removing what they call long, stringy "pus." This mucus is not readily removed in its entirety except by mechanical means with an applicator tipped with cotton, about which it is wound by rolling the applicator between the fingers.

Read before the Ophthalmological Section, College of Physicians, Philadelphia, Dec. 15, 1932.
¹ Lehrfeld, Louis. Vernal Conjunctivitis. Arch. Ophth. 8: 380 (Sept.) 1932.

It is found to be continuous in structure and bound down in the crevices between the follicles in the palpebral type of vernal conjunctivitis. The limbic type, as is well known, has very little mucus.

Microscopic examination of this discharge of the eyes reveals that it consists of mucus containing polymorphonuclear leukocytes, mononuclear leukocytes, eosinophils and epithelial cells.

Realizing that itching is relieved on removal of the mucus, I decided that the treatment should be directed toward rendering this mucus soluble so that it may be readily washed from the eyes. After experimenting over a long period as to the solubility of this mucus, using various strengths of acetic acid, hydrochloric acid, sulphuric acid, sodium bicarbonate, caroid, fibrolysin, chloroform, and sodium ricinoleate, I struck on the use of monohydrated sodium carbonate, U S P.

When the hands are bathed in washing soda, the commercial form of sodium carbonate, the skin becomes very soft, particularly the cuticle about the finger nails. I planned to try it as an agent to render soluble the mucus taken from the eyes of patients with vernal conjunctivitis. As washing soda is a very unstable compound containing ten molecules of water and many impurities, I used the standardized product of the United States Pharmacopeia, containing one molecule of water. I set up a series of test tubes, each containing specimens of mucus from patients with vernal conjunctivitis, at the Wills Hospital and in my private practice. Much discouraged in finding a solvent, I set my rack of test tubes aside, waiting for another inspiration. Some time later I consulted Mr. Joseph W. E. Harrison, an associate of Prof. Charles LaWall of the Philadelphia College of Pharmacy, who by chance was a patient at my office. Picking up a group of test tubes, I asked him if he could tell me in which he would consider the mucus dissolved, if any. He selected the tube containing the sodium carbonate, informing me that the mucus had disintegrated and that a clear solution was not necessary to consider it dissolved.

It then occurred to me that it was unnecessary to have a complete solution of the mucus in order to release its hold on the lid surfaces in vernal conjunctivitis, if the mucus was sufficiently disintegrated so that it might be readily washed away. This could be accomplished by thorough flushings of the eye by means of an eye cup containing any solution pleasant to the eyes.

An alkali such as tenth normal sodium hydroxide is used to render soluble the powdered pollens in making the scratch tests for sensitivity. Sodium carbonate, which is also an alkali and a solvent of mucus, will render soluble the dusts and pollens that enter the eye, along with the mucus to which the dust particles adhere. I felt that with sodium carbonate and the use of frequent flushings of any solution, boric acid for convenience, I would have a treatment that would give the patient relief. I accordingly made solutions of sodium carbonate 5, 10 and 15 grains to the ounce. I found that the solution of 15 grains (1 Gm.) applied to the lids of patients with vernal conjunctivitis was somewhat irritating. Ten grains was tolerated. Five grains caused no complaint on the part of the patient.

In my test tube experiments I used approximately 10 per cent sodium carbonate. This solution, of course, is too strong for the eye, and realizing that it was not necessary to dissolve the mucus completely but merely to loosen it from its attachments, I found repeated use

of this preparation in solution 5 grains to the ounce was sufficient to keep the conjunctiva completely alkalinized and was sufficient to disintegrate the mucus so as to make it readily removable by flushings from an eye cup.

Still working under the theory that thorough and repeated flushings of the eye will wash out the dusts and pollens that could readily be reached on the conjunctival surface, I continued this method of treatment in conjunction with the use of sodium carbonate, three drops, four times a day, the boric acid flushings always preceding the instillation of sodium carbonate.

In order to make sure that the patients were getting sufficient sodium carbonate, I tested the alkalinity of the conjunctiva with litmus paper and found in each instance that the alkalinization had persisted.

Up to the present time I regarded epinephrine as the most effective drug in the treatment of this disease. I learned that epinephrine is disintegrated in the presence of an alkali, particularly sodium carbonate. As a substitute for epinephrine I used cold boric acid solution at a temperature which one commonly finds in the average household icebox, about 55 F., where the solution can be kept. The cold lotion is sufficient to act as an astringent and the boric acid maintains its cleansing effect.

Boric acid, being but feebly acid, does not in any way interfere or render appreciably less alkaline the sodium carbonate. Patients having had the disease for several seasons can comfortably tolerate 10 grains of sodium carbonate in the eyes.

I was agreeably surprised to find that patients were remarkably relieved of the itching and that the discharge gradually disappeared.

Just what effect the sodium carbonate has on the pollens and dusts, I am not prepared to state at this time, but I do know that it enables the ready dislodgment of the mucus which aggravates and intensifies the itching, and that associated with the thorough flushings of the eye with boric acid solution there is effected a rapid alleviation of symptoms and reduction in the size of the follicles.

I do not claim that this treatment will change the pathologic condition in the chronic lid types in which large granulomas exist, because this is a secondary pathologic change which can be removed only by surgery or radium. In the initial stages of the disease, during the first and even the second summers, the pathologic condition disappears when the exciting cause is removed by the treatment just outlined.

It is my belief that the sodium carbonate treatment is not sufficient in itself but must be accompanied with the thorough flushings of cold boric acid solution at least seven times a day. It is sufficient to use three drops of sodium carbonate four times a day, always preceded by the boric acid flush, thus permitting ample time for partial disintegration of the mucus and the theoretical destruction of the active principles in the dusts and pollens which are the causative agents.

Last summer I used this treatment in twenty-seven cases and found that it excelled any other drugs or chemicals heretofore used by me. The disappearance of the discharge, the rapid and complete relief from itching, and the recession of the pathologic condition have been so convincingly striking as to deserve reporting the facts and observations.

I reported the results of my experiments to Dr. John Kolmer, who regards the effects as plausible and hints

that he would not be surprised if the same method of treatment might apply to hay fever

I present this treatment to the ophthalmologic profession only after thorough scientific investigation of the disease, only after proving that desensitization is slow, tedious and oftentimes ineffective in its results, only after observing that radium is of limited use in relief of symptoms and then only in the hands of expert radiologists, only after applying all the known forms of treatment, and only after careful search for a remedy which can be applied throughout the course of the spring and summer months when pollens and certain dusts, influenced by weather, are the exciting agents of the disease

The treatment is not aimed to desensitize, nor is it aimed to prevent the disease. It merely serves as a chemical agent with a rational and scientific basis to render inert the exciting agents, which must be kept frequently flushed from the eyes during the period in which the disease is active

Clinical Notes, Suggestions and New Instruments

DYSINSULINISM A DISCUSSION AND CASE REPORT

JULIAN LOVE, M.D., BROOKLYN
Lieutenant (J.G.), M.C., U.S. Navy

Naming diabetes mellitus on the basis of its aberrant endocrine physiology, one would call the disease hypo-insulinism. In this disease hyperglycemia and glycosuria are essential features. The discovery of insulin by Banting, Best and their co-workers led to the rational therapy of this disease and to the discovery of perhaps two others—hyperinsulinism and dysinsulinism.

Insulin, when given in overdosage to diabetic patients, causes a train of symptoms that is very well known. There is a feeling of nervousness, hunger and weakness accompanied by a profuse sweat, dizziness, diplopia, pallor, faintness, syncope and convulsions, ultimately, coma may result. From this reaction, which is more or less acute in its onset, the patient can be aroused dramatically in a few moments by the administration of carbohydrates.

Seale Harris had noted patients who presented symptom complexes very similar to those obtained in diabetic patients during insulin shock. He was the first to reason that perhaps these patients actually had a spontaneous hypoglycemia of intrinsic origin. In 1924 he¹ reported three cases that had come under his observation, the patients complaining of weakness, nervousness, and hunger one hour before meals, from which relief was obtained by eating carbohydrate in some form. Accompanying these symptoms, blood sugar determinations in every case were below 70 mg per hundred cubic centimeters of blood. He also noted that one of these patients showed evidence of both hyperinsulinism and hypo-insulinism, and to this case he gave the diagnosis of dysinsulinism. Soon thereafter Jonas² reported a case.

These observations were confirmed by Wilder, Allen, Power and Robertson,³ who reported a case in which necropsy showed adenocarcinoma of the islet tissue with metastases to the lymph nodes and the liver. Extracts of the metastatic areas in the latter organ were proved to contain insulin. Similar reports have been made by McClenahan and Norris,⁴ and Thalheimer

and Murphy.⁵ Howland, Campbell, Maltby and Robinson⁶ reported the first cure by surgical means, i.e., removal of islet cell tumor. Cushing,⁷ Womack, Gnagi and Graham,⁸ and Carr, Parker, Grove, Fisher and Larrimore⁹ have also reported successful surgical cures. The Finneys,¹⁰ in operating on their patients, failed to find a distinct tumor and resected a portion of the pancreas, with mild improvement. Warren¹¹ gives an excellent description of adenomas of the islets of Langerhans, and Harris,¹² in 1932, collected all the cases reported on this continent. A case in Germany is reported by Krause,¹³ and more recently John¹⁴ and Heyn¹⁵ have reported cases, while Elias and Turner¹⁶ reported four cases in children. It is interesting that many of these patients have been physicians

REPORT OF CASE

The following is a case which came under my observation

History—S. L., a white man, aged 37, a war veteran, was admitted to the Naval Hospital, Brooklyn, with a diagnosis of diabetes mellitus. He presented none of the complaints given by diabetic patients, except that he was told he had sugar in his urine and that he had lost much weight. He complained of malleolar edema in the evenings, weakness, dyspnea on exertion, and a diarrhea of four or five daily stools with mucus. He also stated that he had weighed 230 pounds (105 Kg.) four years before, while his present weight was 150 pounds (68 Kg.). He had also noted that for the past seven months he had had occasional attacks of weak feeling and haziness, which cleared up immediately after taking orange juice.

A year before he was in this hospital and study showed him to have a chronic ulcerative colitis. He had also had the usual exhaustive study at the Mayo Clinic, and the same condition had been found there. They found a normal blood sugar at that time. His appendix and gallbladder were removed in 1930. The patient stated that he had not had any venereal diseases. He had a submucous resection, after which a perforation of the septum resulted.

His family history revealed no chronic, hereditary or familial disease. The patient's habits were normal in every respect. He indulged in alcohol and tobacco in moderation.

Physical Examination—The patient was pale and undernourished and was not acutely ill. Positive conditions found at examination included pallor of the sclerae and mucous membranes. The skin showed definite evidence of loss of weight. He had a perforated nasal septum and chronically inflamed tonsils. There was a soft systolic murmur at the apex of the heart transmitted to the axilla. There was a slight pitting edema of the ankle. The blood pressure was 102 systolic, 62 diastolic.

Progress—April 30, the fasting blood sugar was 110 mg per hundred cubic centimeters of whole blood. The patient was given small doses of digitalis.

May 2, the fasting blood sugar was 148, the urine sugar, 0.3 per cent.

May 3, the blood sugar was 100, the urine sugar, 0.3 per cent.

May 4, the patient was placed on a diet of carbohydrates 84, proteins 61 and fats 94. The noon urine showed 0.6 per cent sugar, blood sugar, 81.

May 5, the fasting blood sugar was 60. At 11 30 p in the patient had an attack of diplopia, weakness, muscle tremor and sweating, and he became unconscious. He was immediately revived by orange juice. Blood sugar drawn at this time measured 44 mg. The next morning the blood sugar was 112, but the urine contained 1 plus acetone. During the week, a complete blood count and a urinalysis were normal, and the Kahn test was negative.

May 6, the patient had a mild reaction but immediately responded to orange juice.

May 7, a dextrose tolerance test showed the following: Blood fasting, 54, first hour, 476, second hour, 417, third hour, 204. Urine fasting, 0, first hour, 30 per cent, third hour, 20 per cent. A roentgenogram of the heart suggested mitral stenosis. An electrocardiogram showed a depressed ST interval in leads 1 and 3, indicative of coronary involvement.

May 9 and 10, the fasting blood sugars were 56, and just before the noon meal the patient had a slight reaction but, with food, immediately recovered.

May 11, the fasting blood sugar was 68, and fifteen minutes after epinephrine was given by hypodermic it was 100. The diet was changed to carbohydrate 109, protein 66 and fat 119.

May 12, the fasting blood pressure was 68. After 1 cc of solution of pituitary, 68. Daily studies of stools were negative except for 2 plus occult blood. A proctoscopic examination revealed no pathologic changes.

May 14, a barium enema revealed no abnormalities. The blood sugar was 40.

May 16, the blood sugar taken during a reaction, was less than 25 mg per hundred cubic centimeters of whole blood. The diet now was carbohydrate 159, protein 166 and fat 119.

May 17, blood sugars and electrocardiograms were taken simultaneously before and after a dextrose tolerance test. The following description is added. The patient arrived at 8 40 a m, walking and very nervous. He was unable to lie still and sweated profusely. Pallor was very marked. The pulse was 86, and respirations were 20. The patient grew weaker, went into a sort of convulsion and fainted at the conclusion of the test. The blood sugar was less than 25 mg per hundred cubic centimeters of whole blood. At 9 o'clock, he was given 100 Gm of dextrose by mouth. When seen at 10 45, the patient's color was good and he had no symptoms. The blood sugar at this time was 333 mg per hundred cubic centimeters of blood. There was no difference in the electrocardiographic examinations taken with a blood sugar at less than 25 mg or at 333 mg.

May 20, the patient was placed on a regular diet with 8 ounces (240 cc) of orange juice at 8 p m, at midnight and at 6 a m.

June 4, the blood sugar taken during an attack was again less than 25. In the attack he had a rather marked pallor. His eyes were more or less fixed and his skin was cold. He would not answer questions. Attempts to give orange juice were unsuccessful, and it was necessary to give dextrose intravenously. Before the injection was completed, the patient was laughing and joking as though nothing had happened. Investigation revealed that the patient failed to obey instructions and failed to take his additional carbohydrate. This was his last attack while in the hospital.

June 7, The patient's urine contained 1 per cent sugar. A gastro intestinal series of roentgenograms showed a marked widening of the duodenal curve suggesting a pancreatic tumor. There was also a displacement of the bulbous duodenum to the right.

June 9 0.3 per cent sugar was found in the urine, red blood cells numbered 4 million, hemoglobin was 83 per cent.

June 13 2.5 per cent sugar was found in the urine. Antitoxic therapy was instituted.

June 20 the blood sugar was 68. Red blood cells numbered 3.7 million.

June 27, the blood sugar was 50. Red blood cells numbered 3.4 million with 70 per cent hemoglobin. White blood cells 10,000 polymorphonuclears, 67 per cent lymphocytes, 31 per cent. The patient had an acute bronchitis and decompensation returned.

July 1 the patient recovered from his acute infection. Edema disappeared for the most part. The red blood cells numbered 3.1 million, hemoglobin was 65 per cent.

July 11, the patient was seen in consultation with Dr. James Ewing of the Memorial Hospital. He suggested a roentgenogram of the sella turcica and the Aschheim-Zondek test.

July 18, the Aschheim-Zondek test was negative. A roentgenogram of the sella turcica showed no deviations from the normal.

July 27, the red blood cells numbered 4 million, hemoglobin was 75 per cent, white blood cells numbered 6,350.

August 9, the blood count was normal. The surgical consultant recommended exploratory operation, but the patient refused, in view of his recent marked improvement.

August 18, the Aschheim-Zondek test was again negative. The blood sugar was 70.

August 24, the patient was discharged at his own request. The final diagnoses were (1) dysinsulinism (adenoma or adenocarcinoma of pancreatic islets) symptomatically controlled, (2) valvular heart disease and mitral stenosis, no change, (3) chronic ulcerative colitis, (4) chronic myocarditis, class 2a, improved, (5) mild secondary anemia, improved, (6) chronic tonsillitis, no change.

COMMENT

This case is interesting because on three occasions the patient had a blood sugar of less than 25 mg of sugar per hundred cubic centimeters of whole blood. (All determinations were done according to the method of Folin and Wu.) This is the lowest that I have been able to find in any other case reported thus far. Furthermore, this patient could tolerate a hypoglycemia of 50 without symptoms, whereas usually if the blood sugar drops below 70, hypoglycemic or insulin shock ensues. It is another example of bodily adaptability to morbid conditions.

The diagnosis of dysinsulinism is given in this case because in addition to the patient's hypoglycemic reactions, which are due to hyperinsulin activity, when he is given a dextrose tolerance test he shows a typical diabetic response. Moreover, he shows transient hyperglycemia, glycosuria and acetoneuria, which are due to hypo-insulin activity. Either the threshold of insulin production is higher than normal, and when produced is overactive, or else an insulin-like substance is produced which is delayed in its action but which, when acting, has a more powerful effect than normal insulin—a true dysinsulin.

It is my belief that this patient has either an adenoma or, possibly, an adenocarcinoma of the islet tissue. The condition is so well controlled by a frequent carbohydrate diet that he refuses operative intervention. The colitis and cardiac manifestations are believed to be independent of the dysinsulinism, as they seemed not to change whether the dysinsulinism was controlled or not. The colitis at least existed for three and a half years before the onset of the dysinsulinism.

Etiology—These conditions are caused by adenomas or adenocarcinomas of the pancreatic islet tissue. Other endocrine neoplasms, especially of the suprarenal medulla,¹⁷ conceivably might mimic this syndrome. It is also possible that diffuse hyperplasia of the islet tissue might be present in some instances.

Pathology—Anatomically the pathologic changes are those just mentioned. Physiologically, either an overproduction of normal insulin or a true dysinsulin is produced. The hypoglycemia is of course the cause of the clinical symptoms.

Diagnosis—While this is a rare condition, the diagnosis appears to be easy to make. It is clinched by finding a spontaneous hypoglycemia concurrently with the impending or actual syndrome. Whether or not the case is one of hyperinsulinism or dysinsulinism depends on the response to the dextrose tolerance test and on the presence of transient hyperglycemia and glycosuria. In the former, the response to a dextrose tolerance test should be normal or subnormal, and there should be no hyperglycemia or glycosuria. In the latter, the reactions are like those of a diabetic patient. Very often the patients seem to have found themselves that carbohydrates relieve them and present it in their history. The relationship to meals, in that attacks occur soon before meals or when the patient has had a long period without food is almost diagnostically suggestive. In regard to differential diagnosis, it must be remembered in all cases of coma, but more especially with some cases of epileptiform seizures,¹⁸

17 Anderson H B A Tumor of the Adrenal Gland with Fatal Hypoglycemia *Am J M Sc* 180 71 79 (July) 1930
18 Nielsen J M and Eggleston E L Functional Dysinsulinism with Epileptiform Seizures *J A M A* 84 860 863 (March 22) 1930

Treatment—Symptomatically relief is obtained by giving to the patient carbohydrate, by mouth or vein. If none is available, epinephrine by hypodermic should be used. A frequent carbohydrate diet may symptomatically control the condition. A true cure, however, can be expected only by surgical removal of the offending neoplasm. This, however, has not always been found, and partial resection of the pancreas has not given satisfactory results.

CONCLUSIONS

1 A case of dysinsulinism showing both features of hypoinsulinism and hyperinsulinism presented on three occasions a hypoglycemia of less than 25 mg of sugar per hundred cubic centimeters of whole blood. This is the lowest I have seen reported.

2 The basic pathologic condition as well as the etiology is probably adenoma or adenocarcinoma of the pancreatic islet tissue.

3 The patient's symptoms are well controlled by frequent carbohydrate feeding.

COSTOVERTEBRAL DISLOCATION OF THE TWELFTH RIB

W. R. BROOKSHER, JR., M.D., FORT SMITH, ARK.

Dislocation of the ribs at their vertebral articulations is a very rare injury. Textbooks refer to the condition briefly or not at all. The literature is similarly meager in references. Schertlein¹ says that there is but one recorded case in the German literature from 1909 to 1929 and cites Riedinger, who in 1888 compiled nine cases from the literature, of which only one could be regarded as a true luxation. Stewart and Warren² published a review of ten cases and mention two others from

the literature of over 200 years, adding a case of their own. There is the only article on the subject in American literature since 1896 and the latter deals with a dislocation at the sternal extremity.³ Three cases have been reported since then in the German literature.⁴

Separation or dislocation of a rib may occur at its sternal or its vertebral attachment. The displacement may be forward,

Downward dislocation of right twelfth rib

backward, up or down. Approximately one half of the cases reported are of the eleventh and twelfth ribs, which fact is of etiologic significance in that these ribs are not attached anteriorly by cartilage. The anterior ends of the ninth and tenth ribs may be dislocated from their cartilaginous attachments to the adjacent ribs. Dislocation at the costovertebral articulation is most frequently found as a complication of fracture of the spine.

The rarity of vertebral dislocation is due to the firm and strong ligamentous attachments at this site, which make fracture the more likely injury to occur. For the production of such a dislocation, a violent and complex acting force is required. Indirect violence is the principal cause, since its force is transmitted to the costal attachments, although the condition may be produced by direct violence. The degree of violence producing the injury was sufficient to cause death in eight of the ten cases.

4 Schertlein¹, Bohle, W. On Dislocation of Ribs. *Arch. f. Orthop.* 27: 269-272 (May 23) 1929.

reviewed by Stewart and Warren, and in seven of the nine cases compiled by Schwartz.⁵

Complications of pleural and pulmonary injury or abscess formation may be very grave. There may be laceration of the intercostal artery and severe hemorrhage into the pleural cavity.

Roentgen examination will always demonstrate the injury, but it may be noted on physical examination by (1) swelling or depression at the articulation, (2) motility (pressure at one extremity moves the other), and (3) anesthesia or paresthesia with neck rigidity when the first rib is involved. Pain is usually present.

Treatment will of necessity be individualized, strapping or bandaging of the chest appearing to be satisfactory in uncomplicated cases of the lower ribs. Reduction by pressure prior to immobilization can usually be accomplished. In the depressed type, open reduction may be necessary, especially if there is respiratory embarrassment. In the case reported by Stewart and Warren, the first rib was involved and exposure was obtained by an oblique incision over the clavicle. The rib was then drawn upward into the articulation by means of a hook. The brachial plexus and subclavian artery, which had been displaced by the injury with the production of anesthesia, analgesia and paresis, returned to their usual positions and the disturbances disappeared.

The following case, involving a complete dislocation of the twelfth right rib without associated fracture of the ribs or spine or lung injury, is the seventeenth recorded case.

D. P., a man, aged 25, was injured, May 9, 1931, as the result of an accident while driving his car. A front wheel suddenly locked, causing the car to strike an earthen embankment on the side of the road. The car then turned on its left side. The patient was stunned for a short time and he does not know in what manner his injury was received. He proceeded to the office of a nearby physician, who strapped his chest with adhesive plaster after diagnosing fracture of the ribs. The following day the patient consulted his home physician, Dr. Hugh Johnson, through whose courtesy the case is reported. The subsequent progress not being satisfactory, he was referred to me for roentgen examination, at which time the downward dislocation of the twelfth right rib was discovered, as shown in the accompanying illustration. There was no fracture of the ribs or spine. Examination of the lungs gave negative results. A depression was noted at the point of the dislocation, with tenderness on pressure. The patient complained of pain on movements of the arms, when lifting any weight, when stooping or bending and on deep inspiration. Immobilization by means of adhesive plaster was continued, with the gradual disappearance of all symptoms.

LOCALIZED HEADACHE ASSOCIATED WITH LESION OF MENINGEAL VESSELS

WINCHELL MCKENDREE CRAIG, M.D., ROCHESTER, MINN.

Generalized headache, or cephalalgia, may be a symptom of many different diseases and is of doubtful diagnostic significance unless associated with other symptoms of intracranial changes. Localized headache, however, is frequently of diagnostic significance and may indicate the region of intracranial involvement, as illustrated by the case here to be reported.

Intracranial operations under regional anesthesia have demonstrated that the brain is insensitive to pain and that the dura mater is probably the only sensitive tissue encountered, the greatest discomfort is caused by ligation or manipulation of the meningeal vessels.

According to Teachenor,¹ the dura has a rich and somewhat complicated nerve supply. It is supplied mainly from the fifth and tenth cranial nerves and the sympathetic system, although some fibers are derived from the fourth and twelfth cranial nerves. A branch of the mandibular division of the fifth nerve, which is given off directly after the exit of this division from the foramen ovale, and which passes backward to reenter the cranial cavity through the foramen spinosum, accompanies the

5 Schwartz, quoted in Ochsner, A. J. *Surgical Diagnosis and Treatment*. Philadelphia: Lea & Febiger, 2: 228, 1921.

From the Section on Neurologic Surgery, the Mayo Clinic.

1 Teachenor, F. R. Headaches of Intracranial Origin, *Laryngoscope* 37: 320-325 (May) 1927.

middle meningeal artery in its distribution over the dura. This accounts for the excruciating pain when any of the branches of this artery are ligated and would explain a localized region of pain or of tenderness along this artery.

Dandy² has reported the successful treatment of the hemi-crania of migraine by cervicothoracic sympathectomy, and Adson³ has suggested ligation of the middle meningeal artery at the foramen spinosum for the same type of localized headache.

REPORT OF CASE

A man, aged 25, complained of localized headache in the left frontotemporal region. The pain had been present for about one year and had come on suddenly when the man was coughing in the course of an acute attack of coryza. The patient described the pain as a dull ache, with a sensation of pressure, and when he was coughing or sneezing it assumed a sharp, lancinating character, extending forward into the frontal region. About three months after its onset, following a fit of coughing, the pain became so severe that the patient collapsed and was unconscious for a short time.

The anomalous position of the anterior branch of the middle meningeal artery and the operation after which the pain did not reappear.

General examination gave essentially negative results but did reveal a very tender area on palpation in the left frontotemporal region just beneath the insertion of the temporal muscle on the parietal bone. This region was extremely tender to pressure but when the temporal muscle was contracted tenderness could not be elicited. Roentgenograms of the head gave negative results and bruits were not audible. The nasopharynx was apparently normal and cocainization of the sphenopalatine ganglion on the left was not followed by relief of pain. In that the pain was of explosive type, it suggested trifacial neuralgia involving the ophthalmic division of the fifth nerve but no trigger area could be found, and on the whole the condition seemed less characteristic of trifacial neuralgia than of localized involvement of the anterior branch of the middle meningeal artery.

Because the pain was so disabling craniotomy was performed to expose the middle meningeal artery. A small osteoplastic flap was reflected over the left frontoparietal region,

and the anterior branch of the middle meningeal artery was found embedded in the inner table of the skull, where it had eroded a tunnel-shaped passage through the bone rather than the shallow depression usually present. When the osteoplastic flap was elevated, that portion of the middle meningeal artery which was embedded in the bone was torn from its attachment to the dura and remained in the bone. The remaining portion of the middle meningeal artery attached to the dura was ligated, and the dura was incised in a semicircular fashion, as shown in the accompanying illustration. The edges of the dura were approximated with sutures of silk, and the wound was closed. The patient made an uneventful convalescence, and although he complained of localized discomfort in the region of the osteoplastic flap, the former pain had entirely disappeared and he could cough, sneeze, and bend the head forward without any discomfort.

In a letter received from the patient one year after he had been dismissed, he reported that he was completely relieved of headache and was working every day without any discomfort.

HEMIPLEGIA DUE TO SMALLPOX

RAYMOND M. RICE, M.D., AND M. J. CAREY, M.D.
COUNCIL BLUFFS, IOWA

This case is reported because of the evident rarity of its occurrence. In searching for similar cases in the literature we found much discussion of encephalomyelitis following smallpox vaccination.¹ In a thesis dated 1872,² six cases are reported of paralysis occurring during smallpox or convalescence, Goss³ reported a similar case, but none of these were hemiplegias. Mention is made in one modern textbook that hemiplegia due to smallpox has occurred.

REPORT OF CASE

History—A white boy, aged 5 years, was one of five healthy children. The mother had had two miscarriages previous to his birth. He had contracted whooping cough and chickenpox during his third year.

May 27, 1932, he became nauseated, vomited and had a high temperature. The following three days he seemed well, and on May 31 the eruption of smallpox appeared. Two days later his mother noticed that he was unable to walk steadily and put him to bed. The following day she found that he was unable to use his right arm and leg and that his speech was unintelligible. Medical aid was summoned for the first time. He had had no noticeable fever and had seemed perfectly well since his prodromal symptoms.

Examination—The patient was well developed and nourished. The temperature, pulse and respiration rate were normal. An extensive pustular eruption characteristic of smallpox covered his body. He had a complete flaccid hemiplegia involving the right side, including the face and tongue. His speech was thick and difficult to understand. He seemed normal mentally. Hearing, vision, sense of touch and pain all seemed normal. Patellar, achilles and abdominal reflexes were absent on the right side, and the right cremasteric was decreased. All these were normal on the left side. The biceps and triceps seemed equal bilaterally. The pupils reacted normally. The neck was not resistant and the Kernig sign was negative. General physical examination was otherwise negative.

The complete blood count was normal. The urine was negative except for a 1 plus albumin. The spinal fluid cell count was 17, and a slight globulin increase was noted. Wassermann tests of the spinal fluid and the blood were negative.

Progress—Two days after the first symptoms of paralysis were noted, the patient could move his right leg slightly. The third day he was able to raise it off the bed. No change was noted in the right arm until the seventh day, at which time he could move it slightly. On the sixteenth day he was able to walk although the right leg functioned poorly. The arm and hand were very weak and the speech was imperfect. He was again seen about six weeks after the onset, at which time he was almost normal.

Committee on Foods

REPORTS OF THE COMMITTEE

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

VB (VISSCHER BROTHERS) JUNIOR BRAND STRAINED APPLE SAUCE FOR CHILDREN (Sweetened with sugar)

Manufacturer—Lyndonville Canning Company, Lyndonville, N. Y.

Description—Canned, cooked, strained apple sauce prepared from peeled and cored apples with added sucrose, retains in high degree the original vitamin values of the apples used.

Manufacture—The manufacture is the same as that described for VB Old Fashioned Apple Sauce (THE JOURNAL, Aug. 6, 1932, p. 476) with the exception that the pulped, cooked hot apple sauce is strained through a "finishing machine" in an atmosphere of water vapor. The straining operation consumes only a moment of time. The sauce is canned and processed for five minutes. The entire process from the peeling of the apples to the filling of the cans takes approximately eight minutes.

Analysis and Calories—See these sections for VB Old Fashioned Apple Sauce.

Vitamins—The comminution of the apple sauce while still hot in the presence of moisture vapor and the short time consumed make the preparation of this product apparently as efficient as any available for the retention of the natural vitamin values.

Claims of Manufacturer—Especially prepared for infant and invalid feeding.

MILLET'S WHOLE WHEAT BREAD (Contains Whole Wheat, Potato and Rice Bran)

Manufacturer—Millet System of Baking, Dallas, Texas.

Description—A wheat bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p. 817), prepared from whole wheat flour, whole boiled potatoes, water, potato ferment, sugar, rice bran, salt, vegetable compound and compressed yeast.

Analysis (submitted by manufacturer) —	per cent

Ash	2.7
Fat	3.6
Protein (N × 6.25)	9.9
Crude fiber	1.2
Carbohydrates other than crude fiber (by difference)	48.4

Calories—27 per gram, 77 per ounce.

Claims of Manufacturer—Baked one hour.

HURFF BRAND TOMATO JUICE (Made from Whole Red Ripe New Jersey Tomatoes)

Manufacturer—Edgar F. Hurff, Swedesboro, N. J.

Description—Canned pasteurized tomato juice with added salt, retains in high degree the vitamin content of the raw juice.

Manufacture—Field ripened tomatoes from growers in the surrounding territory are inspected for firmness, color, texture and freedom from mold or soft spots. Tomatoes cracked at the stem are excluded. Suitable tomatoes are washed by agitation in flowing water, they are inspected on belts and undesirable fruit is discarded, the ends and cores are automatically trimmed off and the trimmed and cored tomatoes are spray washed. The juice is expressed by a revolving spiral within a stationary screen, the grooves of the spiral are deep at the receiving end and shallow at the discharge end,

which arrangement causes a gentle pressing of the tomato pulp against the screen at the receiving end and a firm pressing at the discharge end. The juice passes through the screen, is brought to a temperature of from 85 to 87 C. in steam jacketed kettles and a small quantity of salt is added. The heating causes entrained air to rise to the surface, producing a froth, which is discarded. The hot juice is automatically filled into enamel lined cans, which are sealed, processed by immersion in water at 90 C. for five minutes and immediately cooled. The usual time period from the cleaning of the tomatoes to the final packing is from fourteen to sixteen minutes.

Analysis (submitted by manufacturer) —

Protein (N × 6.25)	0.8
Crude fiber	0.2
Carbohydrates other than crude fiber (by difference)	4.7

Calories—0.3 per gram, 9 per ounce.

Vitamins—The method of preparation in its details is considered efficient for retaining in high degree the natural vitamin values.

Claims of Manufacturer—This tomato juice is a good source of vitamins A and B and an excellent source of vitamin C, for infant feeding and general table use.

FRANK'S DIATADE

Manufacturer—Frank's Foodless Foods Company, Peekskill, N. Y.

Description—Contains white mineral oil (liquid petrolatum, U. S. P.), whole eggs, malt vinegar, salt, mustard, flour, white pepper and saccharin. Contains no starch and no sugar or fat other than that natural to the ingredients.

Manufacture—The formula proportions of whole eggs and spice are beaten in electric beaters. The mineral oil is added slowly with beating until a satisfactory emulsion is formed. The malt vinegar, salt and saccharin are beaten in. The resultant emulsion is bottled.

Analysis (submitted by manufacturer) —

Calories—0.1 per gram, 3 per ounce.

Claims of Manufacturer—Intended for use in place of the usual salad dressing for table use and for reducing diets. The mineral oil serves as an "internal lubricant" to promote normal bowel function.

FISHER'S WHOLE WHEAT FLOUR (Extra Fine Granulation)

Manufacturer—The Fisher Flouring Mills Company, Seattle.

Description—Fine whole wheat flour milled from a blend of hard red wheats of Montana, Washington and Idaho.

Manufacture—Whole wheat is cleaned, washed, scoured and milled as in preparation of flour. At the end of the process the flour and feed fractions are run together and blended in the same proportions as in the original wheat.

Analysis (submitted by manufacturer) —

Claims of Manufacturer—A whole wheat flour conforming to the United States Department of Agriculture definition and standard.

- 1 TWO STAR DURUM SEMOLINA
- 2 SUPERIOR NO 1 PURE DURUM SEMOLINA
- 3 BIG DIAMOND EXTRA FANCY
NO 1 SEMOLINA
- 4 FANCY NO 1 SEMOLINA
- 5 FANCY NO 1 SEMOLINA

Manufacturer—

- 1 Minneapolis Milling Company
- 2 Commander Milling Company
- 3 Big Diamond Mills Company
- 4 Empire Milling Company
- 5 Northland Milling Company

Subsidiaries of the Commander-Larabee Corporation, Minneapolis

Description—Purified wheat middlings or endosperm milled from durum wheat.

Manufacture—Selected amber durum wheat is cleaned, washed, tempered and milled by essentially the same procedure as described in THE JOURNAL, June 18, 1932, page 2210. The flour middlings is separated out from the bran, germ and flour and packed in bags.

Analysis—(submitted by manufacturer) —

Claims of Manufacturer—For the manufacture of alimentary pastes

EVAN'S E Z BAKE WHITE CORN MEAL (Degerminated and Debranned)

EVAN'S E Z BAKE YELLOW CORN MEAL (Degerminated and Debranned)

Manufacturer—Acme-Evans Company, Indianapolis

Description—Corn meal practically free from corn germ and bran

Manufacture—White or yellow corn is cleaned by the usual grain cleaning machinery to remove foreign material, is tempered with live steam, degerminated by special machines that remove the germ and knock off the pointed end of the kernels, partially dried, and cracked between grinding rolls. The cracked corn is screened, loose bran is removed by air currents, and the corn grits are reduced between steel rolls. The material of desired granulation is separated out by sifters and automatically packed in sacks.

WARD'S BANNER WHOLE WHEAT BREAD (Sliced) (100 Per Cent Whole Wheat)

Manufacturer—The Ward Baking Company, New York City

Description—A whole wheat bread made by the straight dough method (method described in THE JOURNAL, March 12, 1932 p 889) prepared from whole wheat flour, water, sucrose, compressed yeast, salt, shortening and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Analysis (submitted by manufacturer) —

	per cent
Moisture (entire loaf)	38.0

Crude fiber	2.0
Carbohydrates other than crude fiber (by difference)	45.3

Calories—2.4 per gram 65 per ounce.

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standard for whole wheat bread.

FISHER'S COARSE GRAHAM FLOUR

Manufacturer—The Fisher Flouring Mills Company, Seattle

Description—Coarse whole wheat flour milled from a blend of red and white Montana, Washington and Idaho wheats.

Manufacture—Wheat is cleaned, washed, scoured and milled as in preparation of flour. At the end of the process the flour and feed fractions are run together and blended in the same proportions as in the original wheat.

Analysis (submitted by manufacturer) —

	per cent
Moisture	11.1

Calories—3.5 per gram, 99 per ounce

Claims of Manufacturer—A graham flour conforming to the United States Department of Agriculture definition and standard.

FISHER'S WHITE CORN MEAL

(Germ and Bran Removed)

Manufacturer—The Fisher Flouring Mills Company, Seattle.

Description—Finely granular white corn meal practically free from corn germ and bran.

Manufacture—White corn is cleaned of foreign seed and materials, is scoured and polished, broken between steel rolls and passed through purifiers and aspirators, the ground material of a definite granulation and practically free of germ and bran is heat processed to destroy any insect infestation and packed in bags.

Analysis (submitted by manufacturer) —

	per cent
Moisture	11.5
Ash	0.9
Fat (ether extraction method)	2.0
Protein (N X 6.25)	10.6
Crude fiber	0.8
Carbohydrates other than crude fiber (by difference)	74.2

SUNBEAM PURE FOOD TOMATO JUICE (Slightly Salted)

Packer—Tugwell and Wiseman, Inc, Modeltown, Niagara, N. Y.

Distributor—Austin, Nichols and Company, Inc, New York City.

Description—Pasteurized tomato juice with a small amount of added salt, retains in high degree the vitamin content of the raw juice. The same as Blue Bar Brand Tomato Juice (THE JOURNAL, March 11, 1933, p 740).

LUCKY BRAND BREAKFAST FOOD

(Farina with Some Fine Bran)

Manufacturer—Federal Mill, Inc, Lockport, N. Y.

Description—A spring wheat "middling" or farina containing some fine wheat bran.

Manufacture—Spring wheat "middlings" produced in the regular milling of flour is automatically packed in bags.

Analysis (submitted by manufacturer) —

	per cent
Moisture	14.0
Ash	0.71
Fat (ether extraction method)	1.3
Protein (N X 5.7)	11.3
Crude fiber	0.7
Carbohydrates other than crude fiber (by difference)	72.0

Calories—3.4 per gram 97 per ounce

Claims of Manufacturer—This farina is intended for a breakfast cereal or other table uses.

AMERT UNSWEETENED EVAPORATED MILK

Distributor—The Great American Tea Company, New York

Packer—The White House Milk Company, Inc, Mantowoc, Wis.

Description—This canned unsweetened evaporated milk is the same product as White House Brand Evaporated Milk (THE JOURNAL, Nov 19, 1932, p 1780).

SATURDAY, MARCH 18, 1933

DEATHS OF PHYSICIANS PUBLISHED IN 1932

During 1932, the deaths of 3,142 physicians of the United States were recorded in *THE JOURNAL*, as compared with 2,952 in 1931 and 2,943 in 1930. The total number published was 3,247, which includes 105 Canadians. The list includes 2 who died in Hawaii, 1 in Alaska, 3 in France, 2 each in China, Africa and Germany, and 1 each in Persia, Siam, Mexico and Egypt. The obituaries of 87 women physicians were published in 1932, as compared with 84 in 1931. The graduates of medical schools in the United States for the fiscal year ended June 30, 1932, numbered 4,936. Deducting the number of physicians whose obituaries were published, there was a net addition to the ranks of the profession for the year of 1,794, which, figured thus, is an increase of 11 over 1931.

Ages—The average age at death of those classified as of the United States was 64.1, as compared with 63.8 for 1931. Two physicians lived to be 100 years old, and 55 others lived to be 90 or more. One was 22. Twenty-seven physicians died between the ages of 25 and 29, 44 between 30 and 34, 55 between 35 and 39, 114 between 40 and 44, 173 between 45 and 49, 248 between 50 and 54, 420 between 55 and 59, 478 between 60 and 64, 454 between 65 and 69, 419 between 70 and 74, 343 between 75 and 79, 206 between 80 and 84, and 101 between 85 and 89. January was the month of most deaths, with 282.

Accidental Deaths—One hundred and fifty-eight physicians died as the result of accidents in 1932, compared with 139 in the previous year. Automobile accidents accounted for 77 deaths, 6 more than in 1931. In 1932, deaths from falls numbered 19, the second largest number due to accidental causes. Twelve deaths were caused by drowning, 10 each by overdoses of medicine and gunshot wounds, 6 each by carbon monoxide gas, 4 each by skull fractures and burns, 3 each by airplane accidents and poisoning, and 2 each by x-ray machines, explosions and leg fractures. One was killed by a falling business sign, and remaining deaths were

caused by illuminating gas and suffocation by smoke. In some cases the nature of the accident was not specified.

Suicides and Homicides—Eighty-seven physicians committed suicide in 1932, 23 more than in 1931. Shooting accounted for 36 deaths, poison for 23, incised wounds, 9, hanging and gas, 5 each, drugs, 3, jumping, 2, chloroform and stabbing, 1 each, and in the remaining cases the method was not reported. There were 8 homicides by shooting, 1 victim was beaten.

Causes—Heart disease was again the leading cause of death with 1,101 deaths, compared with 1,065 for 1931. Some contributory causes are included in the tabulation, as they have been in former years. A report that the cause of death was "chronic nephritis and heart disease," for example, is so published in *THE JOURNAL* and is reported on the statistical charts under both diseases. Of the deaths from heart disease, endocarditis or myocarditis was specified in 332, angina pectoris in 127, and pericarditis in 2. Cerebral hemorrhage was the second most frequent cause reported, with 346 deaths, 17 additional deaths were reported as due to paralysis. Pneumonia was the third most frequent cause, lobar pneumonia was reported in 225 cases and bronchopneumonia in 59. Fourth on the list was arteriosclerosis, with 259, other diseases of the arteries caused 3 deaths. Nephritis caused 208 deaths, of which 17 were specified as acute nephritis. Of 228 deaths caused by cancer, the stomach and liver were affected in 55 cases, the intestine in 27, the prostate gland in 25, the buccal cavity in 4, the female genital organs in 1, and in 118 the part affected was not specified. Embolism and thrombosis caused 162 deaths, uremia, 81, diabetes, 70, tuberculosis, 68, and other diseases of the respiratory system, 8, diseases of the prostate, 47, and other diseases of the genito-urinary system, 29, influenza, 45, septicemia, 43, senility, 42, hypertension, 37, appendicitis, 35, cirrhosis of the liver, 31, and other diseases of the liver, 8, peritonitis, 24, ulcers of the stomach, 24, and other diseases of the stomach, 7, intestinal obstruction, 23, and other diseases of the digestive system, 30. Other diseases, each of which caused some deaths, were asthma and cholecystitis, 19, pulmonary edema and gangrene, 17, pernicious anemia, 14, abscesses, 12, chronic bronchitis, 12, meningitis, 12, and other diseases of the spinal cord, 1, chronic rheumatism and biliary calculi, 11, brain tumor, 10, paralysis agitans and encephalitis, 9, sarcoma, 8, typhoid, 7, shock, 6, leukemia, hernia and diseases of the bones and organs of locomotion, 5, aneurysm, diseases of the veins, pleurisy, progressive muscular atrophy, secondary anemia and pancreatitis, 4, syphilis, diseases of the organs of hearing, diverticulitis, mastoiditis, carbuncle, agranulocytic angina, septic sore throat, Hodgkin's disease, encephalomalacia, erysipelas and empyema, 3, typhus

fever, aplastic anemia, alcoholism, dementia paralytica, agranulocytosis, multiple sclerosis, sinusitis, edema, Mikulicz's disease, septic cellulitis, paralytic ileus, anemia, lymphosarcoma and intracranial hemorrhage, 2 each. Among other unusual causes of death given for 1 case each were Addison's disease, eclampsia, myasthenia gravis, ruptured esophageal varix, splenic anemia, yellow fever, pancreatic cyst, sprue, and transverse myelitis following the bite of a monkey.

Positions—Among the decedents were 149 who were or had been teachers in medical schools, 264 who served in the World War, 49 veterans of the Civil War and 40 veterans of the Spanish-American War. Eighty-nine had been health officers, 86 members of boards of education and 65 members of boards of health. There were 46 coroners, 46 mayors of municipalities, 24 members of the state legislatures, 12 members of state boards of medical examiners, 17 members of the U. S. Army Medical Corps and 10 of the U. S. Navy Medical Corps. Twenty authors, 14 bank presidents, 13 druggists, 9 postmasters, 8 missionaries, 8 members of city councils, 5 dentists, 5 editors, 2 lawyers, 4 police surgeons, 1 clergyman and 1 judge were included.

Association Officers—The obituaries published in 1932 of physicians who were or had been officers of the American Medical Association included 3 presidents, 1 vice president, 2 trustees, 1 treasurer, 11 section officers and 2 members of councils. Fifteen members of the House of Delegates, including a vice speaker, died during the year. Thirty-two presidents of state societies and 2 state secretaries were included among the officials.

CARBON MONOXIDE IN EVERYDAY LIFE

The changes in living conditions brought about by modern inventions have not always been unmixed advantages. Amid the improvements that contribute to comfort and satisfaction are occasional incidental factors that are not so welcome. Advancing civilization has not been entirely freed from menaces to human welfare, in fact, it has sometimes been directly responsible for the attendant development of new physiologic hazards. A formidable illustration is the increasing danger represented by the colorless and almost odorless gas carbon monoxide, CO. As has often been pointed out,¹ carbon monoxide, except for one reaction, is a physiologically inert gas, it combines with the hemoglobin of the blood to the exclusion of oxygen. Were it not for this one reaction, carbon monoxide would be classed with nitrogen and hydrogen as a simple asphyxiant. Animals that have no hemoglobin are quite normal in 80 per cent carbon monoxide and 20 per cent oxygen. The toxic action of carbon monoxide therefore, is exercised through the anoxemia resulting from the conversion of oxyhemoglobin to carbon monoxide hemoglobin, and the resulting asphyxia.

The facts about the distribution of carbon monoxide should be quite familiar by this time. According to Henderson and Haggard,¹ only in rare conditions does carbon monoxide appear in nature, it is, however, almost universally present wherever man lives and works. It usually originates from the incomplete combustion of carbonaceous material. Illuminating gas is one of the commonest sources of acute poisoning, many of these cases are suicidal. Coal gas, which is made by the destructive distillation of coal, contains from 4 to 6 per cent of carbon monoxide. Water gas, which is made by passing steam over heated coke, contains about 40 per cent of carbon monoxide. In England and the European continent, coal gas is chiefly used for illuminating gas. In American cities a mixture is usually supplied consisting largely of water gas enriched with either some coal gas or petroleum products to afford luminosity and raise the thermal value. Illuminating gas in the United States contains from 6 to 30 per cent or even more of carbon monoxide, generally it is between 20 and 30 per cent.

The "after damp" of coal mine explosions represents a long known modern hazard in which carbon monoxide is primarily involved. More recent is the potential danger of the automobile. The exhaust gas from internal combustion engines, Henderson and Haggard estimate, contains carbon monoxide in proportions ranging from a fraction of 1 per cent to 7 per cent or even higher. The variation depends on the proportion of air and gasoline in the mixture burned, the carbon monoxide increases with increase in the proportion of gasoline, that is, with a rich mixture. A rough estimate of the volume of carbon monoxide that an automobile may produce is 1 cubic foot (28 liters) per minute for each 20 horse power. This is sufficient to render the atmosphere of a single car garage deadly within five minutes, if the engine is run while the garage doors are closed. As has been explained, a man breathing such an atmosphere often falls helpless before he realizes that he is affected, hence many fatalities. In streets where traffic is congested, the content of carbon monoxide rises to about 100 parts per million of air, enough to cause slight headache after long exposure.

In a recent issue of *THE JOURNAL*, Gettler and Mattice² of Bellevue Hospital, New York, remarked that the ideal normal individual should have no carbon monoxide in his blood but that the average person under ordinary conditions is exposed so frequently to it that it is not possible to regard him as being carbon monoxide free unless procedures are employed which are suitable only for the detection of amounts known to be toxic. An effort was therefore made to ascertain what constitutes the "normal" content of carbon monoxide in human blood. In this instance, "normal" obviously refers to the level enforced by the environment of present-day life in various parts of the country.

¹ Henderson, Vandell and Haggard. *H. W. Noxious Gases*. New York: Chemical Catalog Company, 1927. Several of the statements above are taken from this excellent review.

² Gettler, A. O. and Mattice, Marjorie R. *The Normal Carbon Monoxide Content of the Blood*. *J. A. M. A.* 100:92 (Jan. 14) 1933.

A formerly unappreciated contributory factor lies in the components of tobacco smoke, which few persons escape, either because of their own use of smoking tobacco or of their proximity to smokers. Some investigators have regarded the absorption of carbon monoxide from tobacco smoke as negligible, despite the fact that considerable quantities of the objectionable gas are undoubtedly drawn into the mouths of smokers.

In the observations of Gettler and Mattice, the average content of carbon monoxide in the blood of eighteen persons living in New York City under conditions of minimal exposure was found to be 0.27 volumes per cent. This represents about 1 to 1.5 per cent of the hemoglobin combined with carbon monoxide. The average content of carbon monoxide in the blood of twelve persons confined to a state institution in an ideal rural locality was found to be 0.24 volumes per cent. Most of these showed a hemoglobin saturation of less than 1 per cent. The average content of carbon monoxide in the blood of twelve New York street cleaners was found to be 0.69 volumes per cent. This represents about 3 per cent saturation of the hemoglobin with carbon monoxide. The New York biochemists believe that smoking is apt to be the most conspicuous factor in determining the carboxyhemoglobin of an individual under normal conditions when he is not exposed to obvious high percentages of carbon monoxide. The quantities reported for the blood are far smaller than those which give rise to appreciable physiologic effects. Malaise may occur when one fifth of the circulating respiratory pigment is in combination with carbon monoxide. A knowledge of the facts should serve, however, to put us on our guard against an avertible potential modern menace to well being.

Current Comment

MEDICINAL LIQUOR BILL DIES WITH EXPIRING CONGRESS

The Celler-Copeland bill, initiated by the American Medical Association, to establish a rational system of regulating the medicinal use of alcohol, to replace the arbitrary, ill considered system now in force, died with the expiration of the Seventy-Second Congress. The bill, which would have saved the government \$110,000 a year, had the support of the Treasury Department. It had the approval of the Commissioner of Industrial Alcohol and the Director of Prohibition. It was designed to carry out the unanimous recommendation of the Wickersham Commission. It was unopposed by any organized body of prohibitionists. It had passed the House of Representatives, the Senate Committee on the Judiciary had recommended its enactment, and the bill was on the Senate calendar. When a motion was made to take it up for consideration, however, Senator Brookhart of Iowa threatened to filibuster against it during the remaining hours of the session, which marked the remaining hours of his official life, for his

constituents had already retired him to private life at the expiration of the Seventy-Second Congress, March 4. As a filibuster would prevent the Senate from considering not only this bill but any other legislation during the short time remaining to it, the motion to consider the bill was wisely withdrawn. Representative Emanuel Celler of Brooklyn, who introduced this bill in the House of Representatives, worked untiringly to procure its enactment in a form satisfactory to the medical profession. Too much cannot be said in appreciation of his efforts. In the Senate, Senator Royal S. Copeland of New York introduced the bill and stood sponsor for it, and did what he could to procure its passage, but, under the rules of the Senate, against the threatened filibuster he and all his fellow senators were powerless. The bill did not become a law, but the thanks of the medical profession are due Senator Copeland and Representative Celler for what they did in support of the measure.

MENCKEN AND MEDICAL CARE

In the *American Mercury* for March, Mr. H. L. Mencken, who comments pungently on most of the world's affairs, makes public his analysis of the final report of the Committee on the Costs of Medical Care. A considerable number of physicians have written to *THE JOURNAL* requesting that special attention be called to this analysis. Mr. Mencken first expresses concretely the major conclusions of the majority report, namely, that the right way to relieve people of the burden of medical care is to throw that burden on the taxpayers and to convert the doctors into public functionaries. He realizes that the increased cost of medical care has not meant increased income for the physician but that most of the money "has gone to the hospitals, and they have got it, not in the character of institutions for the care and cure of the sick, but in the character of luxurious hotels for the entertainment and flattery of the sick." He emphasizes also the desire to keep up with the Joneses as a part of the reason for the financial disaster associated with hospital bills and particularly in the field of obstetrics. As has been pointed out in these columns, a substantial part of the increased cost of medical service is due to new technics in medical science. On this point Mr. Mencken says:

Not a few of them call for expensive apparatus, and all of them call for kinds of skill that cannot be had for nothing. It is obviously far more costly to make a series of x-ray plates and cardiograms of the heart than it used to be to do the whole job with a stethoscope, or even with the naked ear, as was the custom when I was young. A Wassermann may not cost as much as a permanent wave, but it at least costs more than no Wassermann. And it is plainly more expensive to cut out a gangrenous appendix and nurse the patient back to health than it used to be to give him a dose of Glauber's salts and send for a clergyman.

Mr. Mencken realizes that the problem of the costs of medical care is merely a part of the difficult economic situation in which we find ourselves generally. He calls on physicians to oppose vigorously the attempts that are being made to socialize their profession and he stresses particularly the necessity for restoring the family doctor to the central place in medical practice.

He is not convinced that the formation of groups around hospitals will tend toward this end "The way to restore his old importance," he says, "is to restore his old functions, and that is certainly not going to be done by transferring even more of his patients to the hospitals." While he ends with a tribute to the profession, he also realizes the tendency toward the exploitation of the physician by uplifters in general.

I confess that it always irritates me to hear medical men denounced as prehensile, as is often done, not only by quacks, but also by persons who should know better. They are actually, with very few exceptions, fellows of a vast and innocent sentimentality. The great majority, indeed, might be described with perfect accuracy as easy marks. The men of no other profession are so facily operated on by specialists in other people's duties. They walk into the arms of every new uplifter who happens down the road. My hope is that the report of the Committee on the Costs of Medical Care, with its bald proposals to reduce them to a kind of peonage, will at last awaken them to the fact that they also owe some duties to themselves, and that, with everything else equal, the more they regard those duties the better they will be able to serve their actual patients.

Association News

THE MILWAUKEE SESSION Local Committee on Arrangements

The Local Committee on Arrangements and its various subcommittees under the direction of Dr Stanley J Seeger are actively engaged in perfecting arrangements for the Milwaukee Session. All subcommittees have been appointed and confirmed by the board of directors of the Medical Society of Milwaukee County. Very complete plans have been made for entertainment and for the comfort and convenience of those who attend the session. Dr Harry J Heeb, chairman of the Subcommittee on Hotels reports that the number of reservations already made indicates a large attendance. In order to prevent confusion and to insure good accommodations, hotel reservations should be made at the earliest possible time.

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9 15 to 9 20 a m (central standard time) over Station WBBM (770 kilocycles, or 389.4 meters). The subjects for the week are as follows:

- March 20 Kidney Stones
- March 22 Women Workers and Occupational Diseases

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9 45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

- March 25 Tuberculosis—History and Prevention

Adrenal Ablation and Renal Insufficiency—Our more recent work on dogs demonstrates that renal insufficiency is a constant finding after adrenal ablation and that complete restoration of kidney function follows administration of the cortical hormone with outpouring of urinary nitrogen chlorides, phosphates and other waste metabolites. Significant anatomical lesions have not been demonstrated in the kidneys of animals dying from adrenal insufficiency so it is evident that the renal lesion if such is present is a functional one and occurs in the absence of demonstrable anatomical injury.—Samuel W A and Pittman L L. The Adrenal Cortical Hormone *Medicine* 9:410 (Dec) 1922.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Personal—Dr Hugh C McRee, for years head of the Morgan County health unit, has been appointed health officer of Lee County, with headquarters at Opelika.—Dr John McLaughlin Forney, Tuscaloosa, addressed an open meeting at the University of Alabama School of Medicine, University, January 27, on "The Future of a Medical Career."

ARIZONA

Bill Introduced—H 227 proposes to authorize the state board of health to license persons to practice midwifery. Such licentiates may practice only in cases of normal delivery. They are to be forbidden to make vaginal examinations, to use instruments to aid delivery, to assist labor by any artificial, forcible mechanical means or to administer or prescribe dangerous or poisonous drugs.

CALIFORNIA

Dr Drummond to Give Lane Lectures—Dr John C Drummond, professor of biochemistry, University College, London, will deliver the twenty-fourth course of Lane Medical Lectures in Lane Hall, Stanford University School of Medicine, April 3-7, on "Recent Advances in the Biochemical Study of Nutritional Disorders." Titles of the individual lectures are "Chief Nutritional Disorders of Today How They Have Arisen, Changed Food Habits", "Protein Factors in Nutrition Pellagra", "Fats in Diet and Accessories Accompanying Fats", "Fat Soluble Vitamins," and "Water Soluble Vitamins." Professor Drummond will also give a lecture, April 11, at the university on "General Survey Lines of Future Progress."

Medical History Seminars—The California Medical History Seminar luncheon in honor of George Sarton, ScD, associate of the Carnegie Institution of Washington, D C, was held in San Francisco, January 21. Dr Sarton spoke on "The Slowness of Human Progress." There was also an exhibit commemorating the centennial of the publication of William Beaumont's "Experiments and Observations on the Gastric Juice and the Physiology of Digestion" in Plattsburg, N Y in 1833. At a similar luncheon in December, in honor of Dr and Mrs Charles Singer, London, England, Drs Sanford V Larkey spoke on "Berengario da Carpi" and Emmett L Rivard, "Traditions of Chinese Medicine." An exhibit in observance of the tercentenary of the birth of Antony von Leeuwenhoek was displayed.

COLORADO

Bill Introduced—H 189 proposes to create a board of chiropractic examiners and to regulate the practice of chiropractic. Chiropractic is defined as the science of locating and removing interference with nerve transmission. Licentiates are to be permitted to practice chiropractic, to use such sanitary and hygienic measures as are necessary to such practice, and to use the title of "Doctor" or "Dr" if the word "Chiropractor" or the letters "D.C." follow their names, but they are not to be permitted to practice surgery or obstetrics, or to prescribe or administer drugs or anesthetics. Under certain conditions such licentiates may be permitted to practice electrotherapeutics.

Society News—Dr Archibald J Chisholm, Denver, recently addressed the Colorado Society of Clinical Pathologists on "Relation of Pulmonary Tuberculosis to Anorectal Fistula Clinical, Pathological and Bacteriological Studies"—At a meeting of the Crowley County Medical Society in Ordway, January 10 Dr George B M Baker Rocky Ford, spoke on "Failing Heart in the Aged and Uses and Abuses of Digitalis" and Dr Earnest O McCleary "Necessity and Methods of Relieving the Suffering." Speakers before the society, February 12 included Drs James E Jeffery and William M Desmond on "Reminiscences of Past Medical Practice" and Postinfluenzal Infections, respectively.—Speakers before the Medical Society of the City and County of Denver February 7 were Drs Clarence B Ingraham Jr on "Iridodial Injections to Determine Patency of the Fallopian Tubes" Edward L Harvey, Cesarean Section, James Rudolph Jaeger, Treat-

ment of Brain Injury in the New-Born", Herman G Maul, "Physiology of Blood Transfusion," and Elbert B Swerdfeger, "Esophageal Ulcer"—Medical economics was discussed at the March 8 meeting of the Boulder County Medical Society, Boulder, by Drs John Andrew, Longmont, Oscar M Gilbert and Frank R Spencer, Boulder

DELAWARE

Bill Introduced—H 353 proposes a new medical practice act. The medical council, which now consists of the chief justice of the state and the presidents of the medical society and the homeopathic medical society, is to consist of the chief justice, two members of the medical society, two members of the homeopathic society, and one member of the state osteopathic society. The separate examining boards for nonsectarian physicians and for homeopaths are abolished and a single examining board is substituted, to consist of three nonsectarian physicians, three homeopathic physicians, and one osteopath. By implication, osteopaths are to be permitted to practice obstetrics and surgery if the bill becomes a law.

GEORGIA

Bill Enacted—S 142, eliminating that portion of the medical practice act directing the board of medical examiners to elect a secretary-treasurer from its membership, so as to conform with the terms of an act approved Aug 29, 1931, providing for a joint secretary of the several state examining boards, has been approved by the governor.

IDAHO

Bill Enacted—S 99, prohibiting the possession, sale or distribution of "anhalonium, otherwise known as peyote," has become a law.

ILLINOIS

Bill Introduced—H 433 proposes, in effect, that employees contracting any occupational disease in any employment be entitled to compensation.

Clinic for Treatment of Epidemic Encephalitis—The establishment of a comprehensive clinic for the treatment of epidemic encephalitis at the Dixon State Hospital has been announced. Dr Charles C Rowley will be the resident physician in charge. A small group of children from 6 to 16 years of age will be given special attention. Dixon State Hospital is the only institution in the state where patients with post-encephalitis can be legally committed.

Chicago

General Practitioner's Night—Rheumatism will be discussed in the program to be presented before the Chicago Medical Society, March 22, on "general practitioner's night." Dr Benjamin J Clawson, Minneapolis, will speak on "Etiology and Pathology of Acute Rheumatic Fever", Dr John S Coulter, "Physical Therapy in Chronic Arthritis," and Dr Emil G Vrtiak, "Classifications and Etiology of Chronic Arthritis."

Society News—Dr Charles G Mixter, Boston, will deliver the ninth Lewis Linn McArthur Lecture of the Frank Billings Foundation of the Institute of Medicine of Chicago, March 24, on "Meckel's Diverticulum and Its Surgical Significance."—Officers of the Chicago Orthopedic Club for the ensuing year are Drs Robert O Ritter, president, Jacob K Meyers, vice president, and Daniel H Levinthal, secretary.—Dr Oliver S Ormsby has been elected president of the Chicago Dermatological Society, Dr James H Mitchell, vice president, and Dr Max S Wien, secretary.—Dr Frances R Vanzant, Rochester, Minn, addressed the Chicago Council of Medical Women, March 3, among others, on "Interpretation of Gastric Analysis (Norms of Men and Women)."

Contagious Disease Division for Private Patients—A division for the treatment of private patients with contagious diseases has been opened at the Albert Merritt Billings Hospital, University of Chicago Clinics. Ten private rooms in the Billings Hospital are now available for this service, the number to be increased should the demand warrant it. The division is the only one of its kind in the city since the recent closing of the Durand Hospital. While the Chicago municipal contagious disease hospital and the Cook County Hospital accept indigent patients with contagious diseases, the Durand Hospital, a part of the McCormick Institute for Infectious Diseases, had been the only hospital where private patients with contagious diseases could be isolated. Directors of the institute were forced to close the Durand Hospital because of reduction in income.

INDIANA

Bill Enacted—H 100, giving to all hospitals treating persons injured through the fault of other persons, liens on all rights of action, suits, claims, judgments, settlements or compromises which may accrue to the injured persons by reason of their injuries, has become a law.

Society News—At a meeting of the Adams County Medical Society, January 13, in Decatur, Drs Alois B Graham and Joseph W Ricketts, Indianapolis, spoke on rectal diseases.—Medical economics was the subject discussed before the Clinton County Medical Society in Frankfort, January 5.—Dr John R Brayton, Indianapolis, addressed the Huntington County Medical Society, January 3, on the modern treatment of syphilis.—Dr Murray N Hadley, Indianapolis, addressed the Hendricks County Medical Society, January 20, on diseases of the gallbladder, hernia and appendicitis.—The Wayne-Union County Medical Society, Richmond, heard Dr Frank M Coppock, Jr, Cincinnati, January 19, in a discussion of extra-uterine pregnancy.—Dr John H Warvel, Indianapolis, addressed the Orange County Medical Society at West Baden, March 7, on "Treatment of Anemias."—Dr Robert M Moore, Indianapolis, addressed the Tippecanoe County Medical Society at Lafayette, March 9, on "Cardiac Patient as a Surgical Risk."—The program of the Indianapolis Medical Society, February 28, was arranged for the general practitioner, subjects discussed were obstetrics, anesthesia and urologic problems, with Drs Ernest O Asher, New Augusta, Fred A Thomas and James F Balch, Jr, Indianapolis, as speakers.—Dr Harold Swanberg, Quincy, Ill, addressed the Henry County Medical Society at Newcastle, March 9, on "Radium Therapy in General Practice."

IOWA

Bill Introduced—H 522 proposes that no form of vaccination or inoculation be made a condition precedent to admission to any public or private school or college or to the exercise of any right, the performance of any duty, or the enjoyment of any privilege.

Opposition to Majority Report—That the demands of the constantly changing social structure cannot be met by adhering to the lines advocated in the majority report of the Committee on the Costs of Medical Care was the theme of a resolution unanimously adopted at a meeting of the Woodbury County Medical Society in Sioux City, February 23. The report was discussed by Drs Oliver J Fay, Joseph Brown and Robert L Parker of Des Moines, and William Jepson, Wallace S Petty and James E. Reeder of Sioux City. About 200 physicians, dentists, pharmacists and veterinarians from northwestern Iowa, northeastern Nebraska and southeastern South Dakota attended the meeting.

KENTUCKY

Personal—Dr George L Thompson, Owensboro, has resigned as health director of Daviess County and Dr Lawrence Hubert Medley was elected to succeed him. Dr Thompson is now health officer of McLean County.

LOUISIANA

Personal—Dr Henry Dickson Bruns, emeritus professor of diseases of the eye, Tulane University of Louisiana School of Medicine, New Orleans, was honored recently when a bronze plaque was placed on the door of the diagnostic room for the eye department of the Eye, Ear, Nose and Throat Hospital. This room has been dedicated to Dr Bruns in recognition of nearly fifty years' service in the hospital.

University News—The Commonwealth Fund of New York recently granted \$25,000 to Tulane University of Louisiana School of Medicine, New Orleans, to help in meeting the expenses of the Hutchinson Memorial Clinics for the year 1932-1933. Two of the clinics, those of medicine and surgery, were opened in October. With the aid of the grant, the work was expanded, the *Tulane News-Bulletin* states, and other clinical departments were put in operation as rapidly as possible. Dr Herbert B Rothschild has been appointed assistant in pediatrics in the school of medicine.

MAINE

Bill Enacted—H 217, to amend the law prohibiting the practice of vivisection in schools supported wholly or in part by public money by making a violation of the act punishable by a fine of from \$10 to \$25 and by striking out the provision in the law making it mandatory for the commissioner of education to revoke the certificate of any teacher violating the act, has become a law.

MICHIGAN

Physicians in the Legislature—The following five physicians are serving in the fifty-seventh Michigan legislature

James T. Upjohn, Kalamazoo senate, graduated from the University of Michigan Medical School, Ann Arbor, 1886
Henry E. Perry Newberry, house of representatives, graduated from Michigan College of Medicine and Surgery, 1897 and the Northwestern University Medical School, Chicago 1904
Duncan A. Cameron Alpena, house of representatives, graduated from McGill University Faculty of Medicine, Montreal 1885
John G. Rutison Lansing, house of representatives graduated from University of Michigan Medical School, Ann Arbor, 1903
Edward F. Fisher Dearborn, house of representatives, graduated from Detroit College of Medicine and Surgery, 1906

Graduate Conference—The Michigan State Medical Society and the department of postgraduate medicine of the University of Michigan, Ann Arbor, cooperated in a graduate conference in Saginaw, March 9. The program included talks by Drs. Frederick C. Warnshuis, Grand Rapids, on "Principles in Treatment of Fractures" and "Economic Problems Involving Medical Practice", Richard M. McKean, Detroit, "Nephritis" and "Serology", Robert C. Moehlig, Detroit, "Endocrinological Factors" and "Endocrinological Therapy", Nathan Sinai, Ph.D., Ann Arbor, discussed "Adequate Medical Care". The session was concluded with a round table discussion of "community interest and problems".

MINNESOTA

Bills Introduced—S 743 proposes to accord hospitals treating persons injured through the fault of other persons liens on all claims for damages, rights of action, judgments, settlements or compromises accruing to the injured persons by reason of their injuries. H 1284 proposes to regulate the sale of bakery goods marketed as beneficial for diabetes. Such foods cannot contain gluten or whole wheat flours and must be labeled with a statement of the flour content and that each loaf contains not to exceed 15 per cent of carbohydrate content.

MISSOURI

Personal—Dr. Joseph Mülzer of Heidelberg University, Germany, was guest of honor at a recent reception given by Dr. and Mrs. Carl Barck, in honor of his appointment to the department of ophthalmology at St. Louis University School of Medicine, St. Louis. Dr. Mülzer is the recipient of the Carl Barck Ophthalmology Fellowship, the funds for which were provided by a group of Dr. Barck's friends on the golden anniversary of his graduation from the University of Freiburg, Baden, Germany, celebrated last year.

Graduate Course in Obstetrics—The Kansas City General Hospital began a five day graduate course in obstetrics and gynecology, February 20, consisting of six one hour classes daily, with operative clinics within the hospital. The second day of the course was a joint meeting with the monthly hospital clinic of the Kansas City Southwest Clinical Society. Dr. Wendell M. Long, Oklahoma City, as the guest speaker addressed this session on "Pelvic Infections". Local physicians conducted the course. If the demand warrants, similar courses will be presented later.

Society News—The speaker at a joint meeting of the Jackson County Medical Society and the Wyandotte County Medical Society, Kansas City, February 21, was Dr. Wendell M. Long, Oklahoma City, on "Cancer of the Uterus—Its Prevention and Early Diagnosis".—At a meeting of the St. Louis Medical Society, February 21, Dr. Frank J. Taunter spoke on "Homotransplant of Parathyroid Gland—Preliminary Report of Transplantation of Parathyroid for Tetany of Four and One-Half Years' Duration," and Col. George A. Skinner, Omaha, "Saneness in Maintaining Physical Efficiency". At a meeting of the society, February 14, Drs. George Gellhorn and Lee D. Cady discussed a "New Treatment for Trichomonas Vaginitis" and Charles H. Neilson, "Effect of Weather in Human Conduct and Particularly Its Effect in Disease."

NEBRASKA

Computation of Charity Work—Omaha physicians and hospitals gave free services with an estimated value of \$673,898 to the indigent in 1931, according to a report to the Omaha-Douglas County Medical Society by Dr. Earl C. Sage. The report contrasts this amount with \$450,000 collected by the community chest from the whole city for charity. In tabulating his report Dr. Sage arbitrarily chose a value of \$50 for each surgical operation, \$2 for consultations in outpatient departments, and \$25 a week for medical services in the hospital. Taxpayers contributed for care of this group through funds for the city health department, county hospital

and county physician, \$253,414. In 1926, while he was secretary of the society, Dr. Sage made a similar compilation, which showed that charity work done by physicians amounted to \$476,769, estimated on the same scale as that for 1931.

NEW JERSEY

Bills Introduced—S 226, to amend the laws relating to the practice of osteopathy, proposes, in effect, to permit osteopaths to practice medicine and surgery without restriction. A 289 proposes to prohibit the sale or other distribution of barbitol or any other hypnotic or somnifacient drug, except on the written prescription of a licensed physician, dentist or veterinarian. A 317 proposes to authorize the sexual sterilization of certain socially inadequate inmates of state institutions. A 327 proposes to create a board of naturopathy and to regulate the practice of naturopathy. Naturopathy is defined as that system of the healing art which uses and prescribes the use of the combined psychological, mechanical and material sciences of healing, as taught in legally incorporated schools, institutes and colleges of naturopathy, including psychotherapy, mechanotherapy, internal and external hydrotherapy, electrotherapy, pneumotherapy, neuropathy, physiotherapy, chromotherapy, corrective and orthopedic gymnastics, spondulotherapy, geotherapy, dietetics, biochemistry, phytotherapy.

NEW MEXICO

Bill Passed—H 347, to appropriate \$215,000 to erect and equip a hospital for the treatment of the insane, at Las Vegas, has passed the house.

NEW YORK

Bills Introduced—A 1736, to amend the workmen's compensation act, proposes, in effect, to make compensable any and all disabling diseases and disabling illnesses contracted in the course of any employment covered by the act. A 1737 proposes to create in each public welfare district a central bureau or division of hospital clinics, to promulgate regulations to govern applications for free medical, surgical and other treatment in clinics and in hospitals.

Personal—Dr. Louis C. Kress has been appointed assistant director of the division of cancer control, State Institute for the Study of Malignant Disease, Buffalo. He has been attending physician at the institute since 1920.—Dr. George Herbert Ramsey, associate professor of epidemiology, Johns Hopkins School of Hygiene and Public Health, Baltimore, has been appointed director of the division of communicable diseases in the state department of health. Among other positions Dr. Ramsey has held is that of deputy commissioner of health with the Michigan state department of health. During his affiliation with Johns Hopkins, he spent sixteen months with the West African Yellow Fever Commission under the auspices of the International Health Division of the Rockefeller Foundation.—Dr. Harold Jackson Davis, epidemiologist of the state health department, has been appointed director of medical care for the Temporary Emergency Relief Association. He will represent the department in assisting departments of welfare in the provision of home medical care.—Dr. Allen W. Holmes, Watkins Glen, was recently elected president of the Central New York Roentgen Ray Society at a meeting in Syracuse.

New York City

Afternoon Lectures in Brooklyn—The schedule of Friday afternoon lectures sponsored by the Medical Society of the County of Kings during March is as follows:

Dr. Charles H. Andrew, "The General Practitioner and Eye Conditions"
Dr. Frank B. Cross, "The Patient with Nephritis"
Dr. Joseph B. L. Episcopo, "Disabling Feet"
Dr. Eli Jefferson Browder, "Head Injuries"
Dr. Maximilian A. Goldzieher, "Physiology and Pathology of the Pituitary Gland and Their Clinical Aspects"

Society News—At a meeting of the Medical Society of the County of Kings, February 21, speakers were Drs. Charles Gordon Heyd, on "Problems of Medical Practice and the State Society," and Emil Koffler, "Compulsory Health Insurance Abroad" and Mr. Bailey B. Burritt, "Common Ground in the Next Steps for the Medical Profession and the Profession of Social Work."—At a meeting of the committee on cardiac clinics of the New York Tuberculosis and Health Association, February 28, Drs. Eugene M. Landis, Philadelphia, and John Murray Steele presented papers on "The Movement of Blood Through the Capillary Walls" and "Fever of Unexplained Origin in Heart Failure," respectively.—The twelfth afternoon lecture of the New York Academy of Medicine was presented, February 10, by Dr. Albert A. Epstein, on "Medical and Surgical Complica-

tions in the Diabetic Their Diagnosis and Treatment" Dr William Charles White, Washington, D C, delivered the sixteenth lecture, March 10, on developments in the study of tuberculosis

NORTH CAROLINA

Bills Introduced—S 215, to amend the workmen's compensation act, proposes to make the employer liable for such medical, surgical, hospital and other treatment as may be reasonably required by an injured employee for a period not exceeding thirty weeks from the date of the injury. An injured employee is to have the right to select not to exceed two physicians of his choice, who are to be paid by the employer or by the industrial commission the same fees as are fixed by the medical society in the town or county where the physicians reside. H 765 proposes to require persons employed as nurses, maids, house-workers or cooks to be examined annually by licensed physicians to ascertain whether they are free from venereal disease or from tuberculosis. The bill, however, is to apply only to cities and towns of 1,000 population or more.

OHIO

Personal—Dr Charles A. Neal, Cincinnati, former state health officer, was elected president of the Ohio Public Health Association recently. Dr Gilbert F. Thompson has been appointed surgeon to the Ohio Soldiers' and Sailors' Home Hospital, State Soldiers' Home, to succeed the late Dr John T. Haynes. Physicians of Shelby and Mansfield gave a dinner in honor of Dr Matthew T. Love, Shelby, February 2, in recognition of his completion of fifty years of medical practice. Dr Richard A. Bolt, Cleveland, will leave the first week in April to spend about six months in Germany and Austria studying maternal and child welfare conditions under a grant from the Oberlaender Trust Fund and the Carl Schurz Foundation.

Society News—Dr Samuel Brown, Cincinnati, addressed the Montgomery County Medical Society, Dayton, February 3, on abdominal tumors. Drs Adolph O. Pfingst, Louisville, Ky., and Joseph Stein addressed the Cincinnati Academy of Medicine, March 13, on "Endarteritis Obliterans with Unusual Ocular Findings" and "Treatment of Hay Fever," respectively. Dr Fred W. Rankin, Lexington, Ky., addressed the academy, February 13, on surgery of the colon. Dr Dean Lewis, Baltimore, President-Elect, American Medical Association, addressed the Columbus Academy of Medicine, January 30, on "Arteriovenous Aneurysm." Dr Louis J. Karnosh, Cleveland, will address the Mahoning County Medical Society, Youngstown, March 21, on "Highlights of Brain Function." Dr Edward Starr Judd, Rochester, Minn., spoke, February 21, on acute cholecystitis. The Doctors' Symphony Orchestra of Akron gave a concert in Canton, January 26.

OREGON

Bill Enacted—S 235, providing that the state board of health shall consist of eight members, seven of whom shall be physicians and one a dentist, has become a law.

RHODE ISLAND

Dr Cary Speaks at Annual Dinner—Dr Edward H. Cary, Dallas, Texas, President of the American Medical Association, was the guest of honor at the annual dinner of the *Rhode Island Medical Journal* in Providence, February 20, attended by nearly 200 physicians. Dr Cary discussed economic questions now before the medical profession and Federal Judge Ira Lloyd Letts, questions affecting both the medical and the legal professions. Dr Frederick N. Brown, editor of the journal, was toastmaster. A brief case and a Texas flag were presented to Dr Cary, who was introduced by Dr Norman Darrell Harvey, Providence, president of the Rhode Island Medical Society.

TENNESSEE

Bills Introduced—H 427 proposes that, in the distribution of a decedent's estate, claims for the services of the attending physicians during the decedent's last illness and claims for funeral expenses shall have priority over all other claims, except necessary administration expenses. S 224, to amend the workmen's compensation act, proposes that an employer shall supply an injured employee such medical and surgical treatment as may be reasonably required for thirty days after receiving notice of injury, but the total liability of the employer is not to exceed \$300 for physicians' bills and \$300 for hospital expenses.

Health at Memphis—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended March 4, indicate that the highest mortality rate (179) appeared for Memphis and the rate for the group of cities as a whole, 115. The rate for Memphis for the corresponding week of 1932 was 177 and that for the group of cities, 134. The annual rate for the eighty-five cities for the nine weeks of 1933 was 125, as against a rate of 123 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for a large area or that they have a large Negro population may tend to increase the death rate.

TEXAS

Bill Introduced—S 178, to amend the workmen's compensation act, proposes to require the employer of an injured employee to furnish such medical, surgical and other treatment, nursing and hospital service, as the nature of the injury or the process of recovery may require. Under the present law, the employer need only furnish such services for the first four weeks after an industrial injury.

WEST VIRGINIA

Society News—Dr Henry J. Gerstenberger, Cleveland, presented a "Cinematographic Demonstration of Various Conditions and Diseases of Infants and Children" before the Ohio County Medical Society, Wheeling, February 17. Dr Deryl Hart, Durham, N. C., addressed the society, February 3, on "Treatment of Empyema by Tidal Irrigation." A symposium on tuberculosis was presented before the Raleigh County Medical Society, January 24, at a meeting at Rutherford Sanatorium, Beckley, with the following speakers: Drs George H. Barksdale, and Russel Kessel, Charleston, Tyler R. Boling and George F. Grisinger, Beckley. Drs Walter N. Rowley and John C. Matthews, Huntington, addressed the Logan County Medical Society, Logan, January 18, on "The Place of Low Cervical Cesarean Section in Pathological Labors" and "Fallacies in Urologic Diagnosis," respectively.

Bills Introduced—S 160 and H 536, to amend the laws relating to the practice of midwifery, propose that all persons of good moral character and free from infectious disease who present letters of recommendation from two reputable citizens of the state, by whom they have been employed as midwives, are to be licensed to practice midwifery, without examination. H 511, to amend the chiropody practice act, proposes that all applicants for licensure shall be graduates of reputable high schools and graduates of schools of chiropody recognized by the state department of education as being of the proper standard. H 451 proposes to require physicians making medical or surgical examinations of patients to furnish on demand of their patients detailed reports in writing of such examinations. Every operator or owner of an x-ray machine must, on the request of persons examined, furnish copies of the roentgenograms made.

WISCONSIN

Speakers' Bureau Organized—Seventy Wisconsin physicians have volunteered their services as speakers for county medical societies in cooperation with a speakers' bureau organized by the State Medical Society of Wisconsin, according to a recent announcement. These physicians have offered to speak at county society meetings within a radius of 75 miles from their homes. It is expected that other speakers will be added to the lists as the plan is expanded. Dr Arnold S. Jackson, Madison, is chairman of the committee on scientific work, which arranged the new bureau.

Fifty Years in Practice—Dr Frank S. Wiley, Fond du Lac, was the guest of honor at a banquet, February 20, at St. Agnes' Hospital given by the Sisters of St. Agnes and the Fond du Lac Medical Society, marking the fiftieth anniversary of his entrance into medical practice. Dr Stephen E. Gavin presided and eulogies of Dr Wiley were made by various physicians and other citizens, including Drs Stanley J. Seeger, Milwaukee, Otho A. Fiedler, Sheboygan, Clarence W. Hopkins, Chicago, Frank Gregory Connell, Oshkosh, David V. Meiklejohn, Fond du Lac, and Attorneys L. A. Williams and F. A. Foster. A leather bound testimonial book containing the names of the guests and a complete report of the dinner was presented to the guest of honor. Dr Wiley, who is chief of staff at St. Agnes' Hospital, was graduated from Rush Medical College, Chicago, in 1883.

GENERAL

Negro Health Week—The nineteenth annual Negro Health Week will be observed the week beginning April 2. The celebration is under the auspices of the Tuskegee Negro Conference, the National Medical Association, the National Negro Business League and the National Negro Insurance Association, in cooperation with the U S Public Health Service.

Listing of Specialists—At the annual Congress on Medical Education and Licensure in Chicago, February 13, a resolution was adopted endorsing a plan for the listing of specialists by the Council on Medical Education and Hospitals of the American Medical Association in the manner it now designates those specializing in radiology and pathology. Dr Ray Lyman Wilbur, Stanford University, Calif, chairman of the council, outlined the plan in an address before the congress.

Tri-State Meeting—The thirty-fifth annual session of the Tri-State Medical Association of the Carolinas and Virginia was held in Greenville, S C, February 13-15. Dr Francis B Johnson, Charleston, S C, was elected president to succeed Dr Clarence A Shore, Raleigh, N C, who died three days before the meeting. Vice presidents elected were Drs Charles N Wyatt, Greenville, for South Carolina, John W Davis, Jr Lynchburg, for Virginia, and Foy Roberson, Durham for North Carolina. Dr James M Northington, Charlotte, N C, was reelected secretary. Dr William W Duke, Kansas City, Mo, was the guest speaker, giving an address on allergy at the annual dinner.

Change in Status of Licenses—The Pennsylvania State Board of Medical Education and Licensure recently reported the revocation of the license of Dr Walter W Senn, Williamsport, Nov 30, 1932 because of narcotic addiction. The state board of medical examiners of Arkansas revoked the license of Dr Junius Ruth Rison, at a meeting, Nov 8, 1932, for chronic and persistent inebriety. The license of Dr Benjamin H Smart was revoked, January 3, by Justice Daniel W O'Donoghue of the Supreme Court of the District of Columbia. Dr Smart was convicted on the charge of criminal abortion and sentenced to two years in jail. At a meeting of the Virginia State Board of Medical Examiners, Dec 7-11, 1932, the license of Dr George H Benton, formerly of Coral Gables, Fla, was revoked on account of his conviction for violation of the Harrison Narcotic Act.

Medalist and Lecturer Selected—Alfred Newton Richards, Sc D, since 1910 professor of pharmacology, University of Pennsylvania, Philadelphia will be awarded the Kober Medal for 1933 by the Association of American Physicians during its annual meeting in Washington D C, May 9, in recognition of his work on diseases of the kidney. The medal is provided by the George M Kober Foundation of Georgetown University, Washington, which was created in 1923 by the late Dr George M Kober, former dean of the medical school. Dr Rolla E Dyer of the U S Public Health Service, Washington, has been designated as the Kober Lecturer for 1933 by the Association of Military Surgeons of the United States, under the terms of the foundation. He will deliver the lecture, March 25, at Georgetown University. Dr Dyer became infected with typhus fever last fall from the bite of a rat flea while conducting experiments.

Monograph on the Common Cold—The Pickett-Thompson Research Laboratory of London, England has published a Monograph on the Common Cold. This the eighth volume to come from this laboratory, comprises 699 pages and 51 full page plates, with especial reference to the part played by streptococci pneumococci and other organisms. The need for volumes of this kind is obvious when it is realized that there are at least 50,000 research papers published annually on biologic problems. The authors have reviewed the enormous number of research papers on the common cold and assembled the knowledge that has been acquired by thousands of workers on this subject. This monograph in addition to the review of the literature presents the research of the authors which has covered a period of fifteen years. They have studied intensively a comparatively small number of cases, believing that more information is likely to be obtained by protracted and careful bacteriologic investigations on a small number of persons than by giving less study to each of a much larger number. The authors are convinced that the common cold is not a single definite disease. They believe in the plurality of colds caused by different species of bacteria and that there are pneumococcal colds streptococcal colds colds caused by the influenza bacillus and colds caused by the M catarrhals. Among the chapters in this monograph are the following: The Epidemi-

ology of the Common Cold, The Part Played by Chills in the Causation of Colds, Other Factors Which May Cause a Predisposition to Colds, The Bacteriology of the Trachea, Bronchi and Alveoli, The Bacteriology of the Normal Mouth, The Structure and Physiology of the Nose, The Prevention of Colds and Influenza, Vaccines in the Prevention and Treatment of the Common Cold, Bacteriology of Nasal Sinusitis, and Noncontagious Colds.

FOREIGN

Mental Hygiene Congress—In a list of international congresses to be held in Europe in 1933, published in THE JOURNAL, January 21, page 199, an "International Congress on Mental Hygiene, Rome, in September" was incorrectly included. The next International Congress on Mental Hygiene will be held in Paris in 1935, according to Mr Clifford W Beers, secretary of the international committee. The meeting to be held in Rome, September 27-28, will be the Second European Reunion on Mental Hygiene. Subjects to be discussed at this meeting will be "Mental Hygiene and School," "Extrahospital Assistance to Persons Predisposed to Mental Illness and to Patients Dismissed from Psychiatric Hospitals," and "Importance of the Family for Mental Hygiene." Information concerning this meeting may be obtained from the secretary of the Italian League for Mental Hygiene, Via Masaccio 119, Florence, Italy.

Meeting of Chinese Medical Association—The first general conference of the newly formed Chinese Medical Association was held in Shanghai, Sept 28-Oct 5, 1932 under the presidency of Dr Way-Sung New. This society is an amalgamation of the China Medical Association, founded by and largely composed of missionaries, and the National Medical Association of China, founded in 1915 by Chinese practitioners trained in western medical colleges. Representatives from remote provinces of the republic of China as well as visitors from Manila, Korea and Great Britain attended. Major P G Edge, assistant lecturer in epidemiology and vital statistics, London School of Hygiene and Tropical Medicine, delivered the principal lecture of the conference, on "The Importance of Statistics in Medicinal Research and Practice." Major Edge has been lent for six months to the Henry Lester Institute, Shanghai. The first National Conference on Leprosy in China and meetings of the Chinese Society of Microbiology and the Chinese Physiological Society were held during and immediately following the general conference.

Deaths in Other Countries

Sir William Taylor, since 1922 regius professor of surgery, Dublin University, Dublin Ireland, and from 1927 to the time of his death, president of the Royal Academy of Medicine in Ireland, author of many papers on surgery, suddenly, in Dublin, aged 61.

Government Services

Medical Reserve Officers' Training School

A training period for medical department reserve officers of the army and navy was conducted at Washington University School of Medicine, St Louis, February 12-25, through the cooperation of the faculty of the school and the medical departments of the two branches of the service. The training was also open to officers of the National Guard. The program of clinics was under direct supervision of the faculty of Washington University School of Medicine, and the military instruction under that of Col George A Skinner, surgeon of the Seventh Corps Area, and Lieut Commander Reuben H Hunt, Medical Corps, U S Navy.

W G Campbell Heads Food and Drug Administration

Walter G Campbell, director of regulatory work of the U S Department of Agriculture since 1923, has resigned and that position has been abolished. Mr Campbell will henceforth be chief of the Food and Drug Administration, over which he has had jurisdiction as director of all the department's regulatory work. Secretary Hyde announced that under Mr Campbell's direction the law enforcement activities of the department have now been assigned to the various bureaus so that a director of regulatory work is no longer necessary.

Ignorance of the Ultimate Causation of Disease

In a characteristically philosophic and stimulating address to the Guild of Public Pharmacists, Mr Wilfred Trotter has pointed out how important is the causation of disease and how great is the want of exact knowledge on the subject. The fundamental activity of medical science, he says, is to determine the ultimate causation of disease, but though this sounds like a commonplace it is not kept clearly in mind. The brilliance of the great discoveries that have elucidated the processes of disease tend to obscure the fact that many of them tell nothing about the ultimate causation. Recent progress in knowledge of the internal secretions in the production of symptoms has contributed but little enlightenment in the matter of ultimate causes. Much of the work, though of the greatest value, has been on the physiologic level and has scarcely penetrated fundamental pathology.

A consideration of the actual situation as regards knowledge of the causation of disease reveals that only six agents can be enumerated: injury, malformation, defect of diet, poisoning, infection and neoplasm. Two of these—malformation and neoplasm—are not primary in a strict sense, since in time they will almost certainly be resolved into other factors. Thus only the other four are left. Diseases can be classified into three groups: (1) those which can be assigned with certainty to one of the four causes enumerated, (2) those which have been assigned with more or less probability, and (3) those the cause of which is unknown. The rate at which diseases pass over from the third to the first group is now slow and tends to become slower. Hence the question arises whether a time may not come when the application of known principles to the causation of disease will be at a standstill. Will further explanation depend on the discovery of some new principle comparable to the microbe and the vitamin—the two great developments of the last sixty years? Such common and serious diseases as exophthalmic goiter, diabetes and multiple sclerosis have been investigated for a long time and with increasing refinement of method, yet, however much is learned of their mechanism, nothing is known of their ultimate causation.

In the last sixty years, two wholly new causes of disease have been discovered—microbic infection and vitamin deficiency. The first explained a group of diseases with a certain broad clinical resemblance, but the diseases due to the second show differences of the widest kind, such as those between rickets, beriberi and scurvy. Moreover, the deficiency diseases tend to mimic the diseases caused by other agents, as shown for example, by the resemblance between vitamin B deficiency and alcohol poisoning, each with its acute cerebral symptoms and chronic peripheral neuritis, and by the resemblance of scurvy to an infection. The discovery of deficiency diseases has thus disclosed that allied causes may produce clinical effects showing no hint of any kind of relation and thus made it more difficult to get any hint from clinical phenomena as to new prime agents of disease.

Up to the present, medicine has almost wholly avoided the burden of measurement and made progress by qualitative methods. Perhaps the main harvest of these methods has been garnered and an exact and exhaustive numerical exploration of the facts of disease will have to be undertaken. The practical success and continued progress of medicine tend to obscure the fact that it is without precise data, consisting merely of approximations.

The Cost to Hospitals of Automobile Accidents

The expense of traffic accidents falls with especial severity on hospitals situated on a main road and equipped only for the service of the district. Such hospitals may have their finances deranged by the great demand on their resources for the treatment of injured persons from far and near. In the road traffic act of 1930 a clause was inserted which enables hospitals to recover costs from insurance companies only when the motorist involved is found liable for the accident and when the injured party is an inpatient. At a meeting of the Association of Hospital Officers, Mr C M Power produced figures to show that the hospitals are successful in recovering costs in less than 35 per cent of traffic road accidents treated in their wards, while they are precluded from recovering the cost of treatment of the thousands of automobile accidents treated in their surgeries. When the cost of subsequent outpatient treatment of surgical cases is added, the cost is substantial. An amending bill has been drafted that would enable the hospitals to recover the cost of treating road accidents unless the accident is proved to be due to the negligence of the person injured. Owing to the onus now put on the patient to prove the negligence of the driver of the car and to the fact that the great majority of the patients taken to hospitals are poor and unable to face the possibility of legal costs, the hospitals are placed at a disadvantage in prosecuting claims for maintenance. In the case of children it is seldom possible to obtain evidence to assist parents in their claim for compensation. Figures for eighteen hospitals for 1932 show that the cost of treating 2,692 patients was \$120,000, of which only \$30,000 had been recovered from insurance companies. The constructive proposals put forward were that every hospital should follow up its claim for costs of maintenance and should accept no compromise where liability was acknowledged, that hospitals should endeavor to come to a better understanding with insurance companies, arranging a fixed charge of maintenance with them, and that a panel of lawyers should be appointed to assist patients in the prosecution of claims. It was also suggested that representations be made to the minister of transport on the hardship imposed by limitation of the allowance to hospitals of a maximum of \$125 per patient.

A New Medical Journal The Medico-Legal and Criminological Review

The Medico-Legal Society, which formerly published an annual volume of transactions, has decided to incorporate these in a quarterly medical journal in order that the papers of the society may become available to readers interested in medico-legal subjects soon after delivery. There will also be a review of the medicolegal material appearing in contemporary foreign journals not usually seen by the members of the legal and medical professions. It is also intended to include reports of proceedings of foreign medicolegal societies and reviews of books. The joint honorary editors, Dr Gerald Slot and Mr Everard Dickson, will endeavor to maintain a balance between the medical and legal aspects, so that the material provided will be useful to both physicians and lawyers. The *Review* will be issued free to members of the Medico-Legal Society; for others the annual subscription will be \$3 per annum. The publishers are Balliere, Tindall & Cox, Henrietta Street, London, W C 2. The principal papers in the first issue are on "Medico-Legal Practice," by Sir John Collie (an authority on malingering in this country) and the "Medico-Legal Significance of Impotence in the Male and Female." The abstracts are a valuable feature. They are classified into the following sections: criminal and social prophylaxis (sterilization of defectives), drunkenness and its medicolegal aspects, forensic obstetrics, forensic psychiatry and psychology, injuries, insurance medicine, occupational diseases, paternity and blood grouping, poisoning, therapeutic accidents and medical negligence, violent

death from physical causes. The new journal should certainly supply the wants of physicians, lawyers and others interested in medicolegal subjects. It is the only journal dealing exclusively with these subjects published in the English language.

The Veterans, the Budget and a Tax on Physicians

The difficulties the government is encountering in endeavoring to balance a budget that shows now a deficit of more than \$450,000,000 compel it to seek new sources of revenue. Everybody believes that the deficit is due to the extravagance with which, during the recent prosperous years, the ministries increased the salaries of civil servants, pensioned large numbers of persons, and created a ruinous social insurance system and retirement at age 50 for all old soldiers not only of the World War but of all the campaigns carried on by France in the colonies, in Syria and in Morocco, since 1870. The total number of veterans is 4,000,000, and the number is increasing every day, owing to the fact that, through political favoritism, persons who never left their homes are granted pensions as ex-service men. The government sought to reduce by merely one tenth all the salaries and pensions, but it encountered formidable resistance, supported by the members of parliament for whom all these beneficiaries constitute a powerful electorate. It has not had the courage to suppress the compulsory social insurance system, in spite of the evidence of its destructive effects. It has preferred to seek an increase of the revenue from the existing taxes and duties, and contemplates more particularly increases in the taxes paid by the liberal professions—the lawyers and the physicians. The latter especially appear to be singled out. They are accused of always making inaccurate declarations of their professional income, owing to the fact that the government cannot exercise any adequate supervision of their revenues. The physician who receives a fee from his client in his office enters, it is alleged, whatever he likes in his financial record. The law has supported him in his refusal to open his records to the inspection of the agents of the national treasury, since the right of privileged communication entitles him to keep secret the names of his patients. The financial minister is contemplating requiring the physicians to issue clients' receipts for all sums paid to them, and to fill out, at the same time, stubs showing the amount received but omitting the name. The stubs would be checked up, each year, by the agents of the national treasury. The Confederation des medecins de France immediately filed an energetic protest against any such project which would incite the discontented client to become an informer against his physician, in case the latter had committed any irregularity in making out the receipts or the stubs. Furthermore, every physician gives a large number of free consultations to members of his family, to his friends and in the dispensaries. It has been suggested also that every prescription of a physician in order to be filled by a pharmacist be required to bear a stamp supplied by the physician, the denomination of the stamp to vary with the amount received for the consultation. These stamps would constitute a special tax imposed on the physician. The pharmacists themselves protested against such an innovation as physicians would be inclined to write fewer prescriptions. Finally, it has been suggested that a special tax be levied on the physician the amount to be determined by the fiscal agent on the basis of his presumed income and his mode of living—amount of rent paid, number and style of vehicles, number of servants and the like. In case of disagreement a special commission including a physician, would establish the probable amount of income. But such a basis would result in numerous forms

of injustice, since the rent paid by the physician depends on the size of his family, whereas these expenditures may be supplied by his personal fortune and that of his wife, which in some instances would exceed by far the strictly professional income. That is true particularly in the case of well-to-do physicians who have few clients and who devote themselves chiefly to scientific researches. At all events, the medical profession is being threatened with various unjust proposals.

The Contagiousness of Epidemic Encephalitis

Although epidemic encephalitis is still obscure as to its origin, there appears to be no question about its being contagious. Addressing the Societe des medecins des hopitaux de Paris, Mr. Renaud, and later Mr. Netter, emphasized the long period during which patients who have recovered or who have become affected with Parkinson's disease remain germ carriers. They cited numerous cases in point, particularly cases of parkinsonism of long standing. How the contagion is transmitted is not known, but it appears to require peculiar conditions. The presence of marked changes in the interacinous spaces of the salivary glands leads to the assumption that the saliva plays a rather important part as a vehicle of the contagion. Mr. Etienne Bernard recalled a case of acute edema of the lung, which he observed, together with Mr. Bezançon, in a case of encephalitic parkinsonism of long standing, in which there appeared to be a new attack of encephalitis at the site of the bulb. The anatomic studies in this case pointed in this direction. Mr. Comby cited a case of late familial contagion traceable to a patient with parkinsonism.

The Difficulties of Public Health Work

One of the obstacles to an efficient organization of public health work in France, where the depopulation is due to the excessive mortality, lies in the law, which gives too much power to the municipal councils. The members of these councils, who are elected by the voters, regard it their principal duty to see that the taxes are not increased. In most of the rural communes, the members of the councils refuse to entertain any suggestions that might compromise their reelection. Hence, they are absolutely indifferent to the hygienic conditions, and are not willing to consider plans for the improvement of the water supply or for the creation of dispensaries.

BERLIN

Feb 6, 1933

The Gas Menace in Hospitals

In the Charite Hospital in Berlin, some 200,000 roentgen films are stored. The surroundings are as nearly fireproof as human ingenuity can make them, but if a fire should break out, one must be prepared to combat a possible menace of gas. In an address on "Gas- und Luftschutz," Dr. Kuhnert, the superintendent of the Charite Hospital, called attention to this menace. He had invited a number of experts to hear a report on the subject of protection against poisonous gases, presented by the hygienist Stabsarzt Dr. Otto Muntsch. Muntsch is the author of a well known work on diseases caused by war gases. His address included tabulations, statistics, preparation and demonstrations of gas protection apparatus. The hospital, he stated, is the place to try out apparatus for gas protection. In view of the recent phosgene catastrophe in Hamburg, and the more recent disorders caused by poisonous gases in Belgium, gas protection has become more important. Muntsch described the symptoms of poisoning by the various gases, as well as the means of defense. The people must be instructed as to the effects of poisonous gases, in order that they may adopt prophylactic measures. The hospitals should not only provide suitable apparatus for treatment of gassed persons but also introduce special courses for the training of physicians in

the care of these patients. To protect patients in hospitals, measures must be adopted against dangers arising from gas attacks and conflagrations. The prophylaxis will vary with the location of the buildings and the type of construction. The gas protection crews, provided with masks and resuscitation apparatus, must be trained so that, if suddenly needed, they will be able to transport patients to safety. There were many pessimistic enough to assert that prophylactic measures would be of no aid.

Multiple Sclerosis and Heredity

One of the younger investigators in the field of heredity, the internist Curtius at the University of Heidelberg, has published the results of his research on multiple sclerosis in relation to heredity. He studied the families of 106 multiple sclerosis patients. More than 52 per cent of the living persons were examined in person, and nearly 90 per cent of the relatives could be studied exhaustively. His statistics consisted of an unselected collection of material and computation of the corrected percentages in accordance with the Rüdin-Weinberg-Luxenburger method. A comparison of his statistics was made with similar values in the average population and also with the "average population" of Luxenburger and Schulz. The comparative values in the multiple sclerosis families and the average population according to Luxenburger, for schizophrenia, were 1.27 and 0.90, for manic-depressive insanity, 1.22 and 0.30, obscure psychoses, 1.44 and 0.80, dementia paralytica, 0.99 and 1.24, cerebrospinal syphilis, 0.22 and 0.28, epilepsy, 1.10 and 0.18, senile dementia, 4.32 and 0.54, dementia arteriosclerotica, 2.93 and 0.35. On the whole, the frequency of disorders of the nervous system in the multiple sclerosis relatives was from two to three times as great as in the normal population. The degree of consanguinity ran parallel with the intensity of the hereditary taint. The taint in the multiple sclerosis families consists essentially of such hereditary anomalies as epilepsy, weak-mindedness, hereditary tremor, hereditary hardness of hearing and hereditary nystagmus. Hereditary predisposition plays an important part in the genesis of multiple sclerosis—with which is associated possibly an exogenic factor, or causative agent. Further scrutiny of the results of this research by comparison with other similar material is needed.

Financial Condition of the Sick Benefit Associations

A question much discussed is whether the increase in the number of members of the sick benefit associations who are unable to pay their dues will lead to serious difficulties affecting the financial situation of these associations. Mr. F. Okrass, a director of the chief league of German sick benefit associations, has made a public statement to the effect that he does not share the pessimistic views commonly heard, even though conditions have made necessary certain restrictive measures. At the end of the first quarter of 1932, the total receipts from membership dues showed a deficit, as against the expenditures, of 0.85 marks (21 cents) per member, but the total receipts exceeded the expenditures by 0.65 marks (16 cents) per member. Expressed in percentages of the total expenditures, medical treatment for the first quarter of 1932 required 20.0 per cent as compared with 17.6 in the first quarter of 1931, medicines and other remedies required 11.1 per cent as against 10.5 per cent, hospital care, 14.2 per cent as against 12.9 per cent, and sick benefits, 27.1 per cent as compared with 33.3 per cent. At the end of 1930, the funds held by the Ortskrankenkassen (local associations) amounted to 39.93 marks (\$9.50) per insured member, the Landkrankenkassen (provincial associations), 18.05 marks (\$4.29), the Betriebskrankenkassen (industrial associations), 65.69 marks (\$15.63), the Innungs-krankenkassen (guild associations), 40.93 marks (\$9.74), and the Knappschafts-krankenkassen (miners' associations), 143.59

marks (\$34.17). Owing to the type of the invested funds, the assets of the sick benefit associations represent, however, in reality a much lower sum than the book values.

Physicians in the Service of Municipalities

There are many physicians in Germany who are engaged by municipalities and various organizations. Their compensation is not large but usually suffices to cover their most necessary expenditures. This class is beginning to feel the pressure of the economic situation. After the deliberations of the hospital physicians with the employers' leagues of Germany had failed, the government-appointed arbitrator of the two parties called a meeting for January 18 to reach an understanding. The representatives of the assistant physicians were ready to make concessions, but the attempt to effect a compromise failed owing to the endeavor of the employing organizations to introduce a different method of payment. These organizations insisted on the introduction of a cash payment in addition to maintenance, in order to be able to compensate the nurses in the same manner. The assistant physicians, however, held that the mode of payment that has been in general use (classification in the group compensated in the manner provided for university men) is correct and that it has proved its value in recent years. As the contending parties could not reach an agreement, the arbitrator Professor Brahn declared the deliberations closed.

ITALY

(From Our Regular Correspondent)

Jan 15, 1933

Sanitary Conditions in Italy

The incidence of infectious diseases in Italy has shown an improvement in recent years. The number of cases of smallpox and varioloid, which in 1921 was 4,644, dropped in 1929 to 6 and in 1930 and 1931 to 0. The decrease is doubtless due to vaccination against smallpox, and revaccination at the age of 8, which have been made compulsory.

In 1921 there were 35,527 cases of typhoid and paratyphoid infections, after which there was a steady decline to 24,682 cases in 1931.

Tropical diseases have been virtually eradicated. Of exanthematic typhus there were only a few outbreaks in 1921, 1926, 1927 and 1928. No cases of cholera were observed during the decade. Small outbreaks of plague occurred in 1921 and 1922. There have been no cases since 1927.

Sanitary legislation has been developed and includes compulsory notification for a greater number of infectious diseases, compulsory antityphoid vaccination for certain groups particularly exposed to contagion, and antidiphtheritic vaccination with the Ramon anatoxin. In the chief city of every province, a laboratory of hygiene and prophylaxis has been established. A control of serums, vaccines and arsphenamines has been provided. The regulations pertaining to the supervision of milk and the compulsory crusade against flies have been revised.

Congress of Neurology

The Società italiana di neurologia held recently its ninth national congress in Modena. The single topic on the program was "Present-Day Conceptions of the Physiopathology of the Extrapyramidal System." The official speaker was Professor De Lisi, director of the Clinica neurologica of the University of Cagliari. He emphasized that an extensive revision of the theories pertaining to this subject was needed. For example, there has been advanced the conception that the fundamental function of the extrapyramidal system is postural tonus. Adequate demonstrations of the mechanism of this function have not been given. The interpretation of pathologic movements has thus far been dominated by the theory of localization and many attempted solutions are now recognized as false or at least too categorical. Chorea, regarded as of striatal origin,

is attributed rather to anomalous cerebellar stimuli applied to the sensomotor cortex.

The problem of hyperkinesia requires for its explanation knowledge not yet acquired of the essential nature of nervous energy.

In studying the function of the extrapyramidal system, as regards the coordination of postural activity and myostatic innervation, the action of the cerebellum must be considered. The study of extrapyramidal changes in psychosis and of psychopathic and neurovegetative manifestations in extrapyramidal diseases has brought out many points of analogy and has confirmed the conception of an intimate correlation between extrapyramidal, neurovegetative and psychic functions. Hence, "extrapyramidal" is not solely an anatomic term but represents a wide physiologic and clinical conception, concerning the precise aspects and limitations of which it would be useful to reach an agreement.

Numerous communications were presented. Lugaro of Turin gave an account of his research on the question of the medullated and amyelnic nerve fibers in the posterior roots. Mazza of Reggio nell'Emilia reported his research tending to refute the tuberculous origin of dementia praecox. Donaggio of Modena explained a new urine test, applicable also to the cerebrospinal fluid.

The congress passed a resolution urging the government to include neurology among the required subjects for the government examination in medicine. Professor Tanzi was chosen as honorary president and Professor Donaggio as active president of the society. Rome was chosen as the place of the next congress.

Professor Bruschettini

The death of Prof. Alessandro Bruschettini, bacteriologist of Genoa, has been announced. He studied rabies and tetanus and was the first to affirm that the toxin of tetanus, just as the virus of rabies, is transmitted from the point of infection to the nerve centers along the nerve paths. He was among the first to advocate vaccino-therapy and he manufactured a plurivalent antipyogenic vaccine. In recent years he occupied himself almost exclusively with problems concerning immunity to tuberculosis.

BUDAPEST

(From Our Regular Correspondent)

Feb 7, 1933

New Rules for Writing Prescriptions

The Ministry of Public Health issued a booklet, compiled by Dr. Joseph Melly, with the title "The Duty of Practitioners Toward the Magistrates," which contains some new rules for the filling of prescriptions. The main paragraphs are as follows: 1. The prescribing of drugs necessitates that prescriptions be signed with the full name of physicians. In urgent cases any plain paper may be used but, as a rule, prescription blanks shall bear the printed full name and address and the telephone number of the physician, particularly in the prescription embodies drugs that are declared in the pharmacopoeia to be poisons. If drugs are ordered which are marked in the pharmacopoeia as + or ++ poisons the physician is obliged to give in writing full directions. It is strictly forbidden to write according to directions' or instruction'. Pharmacists must not deliver poisonous drugs so prescribed. Prescriptions containing poisons designated by two crosses if for the residents of villages where there is a pharmacy, may be prepared and delivered within two days where there is no pharmacy, within four days. Medical prescriptions in which two cross poisons are ordered may be renewed by pharmacists only in case the renewal is ordered by a physician by inserting the word's *repetitur* or *renewitur* and his signature and the new date. If corrosive mercuric chloride is prescribed, the pharmacist has to retain the prescription and register it in his

poison ledger with a serial number. Pharmacists have to retain also all prescriptions that call for excessive dosages. These have to be registered and kept for at least ten years. Patients are entitled to copies of the prescriptions, but the word "copy" has to be displayed on them.

The Bacteriologic Institute

The city of Budapest built a magnificent bacteriologic institute, which attracts visitors from all parts of the world. Recently the institute issued its first report, embracing the work done in 1931. Owing to the small number on the staff, the ever increasing examinations can be done only by indefatigable work on the part of the personnel. The institute examines bacteriologically the city water and has undertaken to make plans for supplying water to the new suburbs of greater Budapest. The bacteriologic examinations of ice justified the campaign started by the chief medical officer against the use of natural ice. On the initiation of the chief medical officer, the institute started the supervision of all dairies of the capital and carried on research on the city's atmosphere.

The overwhelming amount of material to be tested is the result of the compulsory bacteriologic examinations which were recently required. In 1931 the institute made 3,380 tests for diphtheria, 8,141 tests for typhoid and 9,839 Wassermann tests. Besides numerous other tests, the institute produced 6,000 doses of scarlatina streptococcus vaccine and collected measles reconvalescent serum. Two physicians of the establishment made 20,000 protective inoculations against diphtheria on children.

Efforts to Improve Obstetrics

The recent statement of Max Hirsch, professor of obstetrics in Berlin, that there had been no practical achievement in the field of obstetrics in the last thirty years, was significant. Hirsch suggested the remedy that all confinements which from the beginning promise to be abnormal should be terminated by cesarean section. Dr. Burger, assistant to Professor Frigyesi of the first obstetric clinic of Budapest University, reported in the *Orvosi hetilap* his results in the clinic in 117 cesarean sections. He endorses Hirsch's proposal. He believes that the indications for forceps need revision, better results may be achieved if their use is not excessively restricted but the indications are amplified on scientific grounds. Still better results may be achieved if in certain cases, after thorough consideration, cesarean section is decided on earlier than usual.

These conclusions are logical not only because the results in obstetrics are far from ideal but because of the ever growing number of elderly primiparas as a result of the present social and economic conditions. It would be unwise to impose on these the risk of a so-called trial labor as was done before the war. It must not be forgotten that the majority of pregnant women at present are forced to work in their own homes or outside and thus they feel the disadvantages of pregnancy to a greater degree. From a rational point of view this question is of first importance, because, owing to the desperately low birth rate of almost all European countries, it is the supreme duty of physicians to save the life of mother and child.

Influenza in Hungary

The present influenza epidemic has made its appearance in Budapest and in one or two other large cities. The cases are fairly mild. The incidence in Budapest recently was so great that several schools, offices and warehouses had to be closed. Some of the cases resemble acute food poisoning, being associated with vomiting, diarrhea and tenderness in the right iliac fossa. Parts of Hungary, chiefly the lowland, are free of the epidemic. According to late reports, influenza has spread through Rumania to Bulgaria and Greece. Although the number of cases of respiratory disease has been rising in Bucharest, there is as yet little evidence of an outbreak.

VIENNA

(From Our Regular Correspondent)

Jan 15, 1933

The Jewish Population of Vienna

In a publication on the Jewish population of Vienna (numbering 200,000) are figures that permit a comparison with the data on the non-Jewish population (1,600,000). The births among the Jewish population during the four-year period 1928-1931 were 1,362, 1,343, 1,222 and 1,064, respectively, which reveals a constant decrease over this period, the fourth year showing a diminution in the birth rate of nearly 25 per cent. The deaths for the four years were 2,669, 2,710, 2,598 and 1,735. In comparison with the non-Jewish population, whose births declined during the period only 16 per cent, the decline among the Jewish population was almost one half greater. The mortality in the two sections of the population was almost equal, being about 13 per thousand. However, the mortality according to age groups shows marked differences. The mortality of Jewish children under 12 months of age was 67, 55, 37 and 36, respectively, or 25, 2, 15 and 15 per cent of the total general mortality, as compared with a percentage about three times as high among the non-Jews. The deaths among the Jewish population in the 80-90 age group were 197, 223, 196 and 240, respectively. In general, many more women than men attain age 80. The corresponding percentage among the non-Jewish population is below 6 in the 80-90 age groups. The age groups 50-60 showed a higher mortality among the Jews, the deaths constituting about 23 per cent of the total mortality, as compared with 18 to 19 per cent among the non-Jewish population. In both classes of the population, however, the women of these age groups show a greater resistance than the men, whereas in the age groups 30-40, in both classes, the women show a higher mortality than the men. There was no great difference in the causes of death, except that mental disorders were somewhat less frequent among the Jews and disorders of metabolism were more frequent than the average for the whole republic. The increase in the number of deaths from neoplasms and from circulatory disturbances corresponds to the general average, but the increase in leukemic conditions is noticeable. Tuberculosis is comparatively rare among the Jews, only from 6 to 7 per cent of the deaths are due to tuberculosis, as compared with from 10 to 11 per cent in non-Jews. During the past ten years the Jewish population of Vienna has decreased (70 per cent of all Austrian Jews reside in Vienna) by 20,000, or 10 per cent of the total Jewish population, whereas Vienna's general population has declined only 3 per cent. Unless something brings about a radical change, a total annihilation of the Jewish population within sixty years is certain.

Chemically Pure Vitamin C

At the last meeting of the Vienna Biologic Society there was great surprise at the announcement of Prof Dr A. Szent-Gyorgy of Szeged that he had succeeded in isolating vitamin C in a chemically pure crystalline form. Szent-Gyorgy obtained from the suprarenal cortex a substance of crystalline form that he terms "hexuronic" acid, which research has shown is identical with vitamin C secured from plants. By chance, Szent-Gyorgy experimented with the paprika plant, which is so widely used in Hungary. In this plant so much hexuronic acid was found that large quantities could be obtained, which made it possible to establish beyond all doubt its absolute identity with vitamin C. The chemical structure of these two identical substances is $C_6H_8O_6$. There are probably intimate relations between vitamin C and pigment metabolism, which require further explanation. Freckles, naevus pigmentosus, vitiligo and other disturbances of pigmentation can now be studied experimentally to greater advantage. Research to confirm Szent-

Gyorgy's discovery is being carried out in Switzerland. In Vienna and in Germany experiments are being done to determine the relative effects of hexuronic acid and the substance known as vitamin C.

Seventieth Birthday of Professor Pal

Prof Jacob Pal—teacher and physician—is known throughout the medical world. His seventieth birthday gave his numerous friends a welcome opportunity to honor him by the publication of a large memorial volume. Pal's chief research concerns investigations on the respiration, heart and circulation. The term vascular crisis originated with Pal. His publications on the smooth musculature of the blood vessels, hypertension, the relation between the sympathetic nerve and tonus have made his name known afar. He has purposely avoided honors, that he might work the more. Nevertheless, he has been sought out frequently by learned societies and has become the recipient of many distinctions.

The Treatment of Tachycardia

In connection with a graduate course for physicians in the Medizinisches Seminar, Prof L. Braun spoke recently on the treatment of tachycardia, which has become so frequent. One distinguishes "sinus" tachycardia, which arises from the sinoauricular node, and the auriculoventricular type, which is associated with auricular flutter and auricular fibrillation. The former type is found in association with fever, excitement or muscular work but seldom ranges above 120 to 160 beats per minute. It is frequently influenced by the respiration. It usually subsides gradually but may subside suddenly. Flutter tachycardia is increased by work, and as a result of alternating "blocking" and "deblocking" there is an irregular pulse. The treatment of all forms of tachycardia was originally purely symptomatic. It is often possible to stop a paroxysmal auricular or ventricular tachycardia by pressure on the vagus nerve, and also by the Valsalva experiment. Relief is sometimes afforded by cold applications to the precordial region, by injections of pilocarpine or physostigmine, or by intravenous administrations of digitalis or strophanthin. Quinine may be regarded as a specific but must be used cautiously because it has also a paralyzing effect on the heart muscle. Quinine hydrobromide is probably the best remedy, given several times a day in from 0.25 to 0.5 Gm doses (4 to 8 grains). If one desires to use intravenous quinine therapy, the patient must be carefully supervised. Digitalis has a good effect in nonparoxysmal fibrillation and often also in the case of flutter. Many patients with paroxysmal tachycardia are aware of the approach of the attack several hours in advance. In such cases, one can prescribe to advantage quinine prophylactically in rather large doses (0.5 Gm several times a day).

Increase of Infectious Diseases in Austria

During the past two months, a marked increase in the number of new cases of diphtheria, measles and scarlet fever has been noted in all parts of Austria but more particularly in the rural districts. The epidemic, for that is what it amounts to, is distinguished by its relatively mild type, but the reports agree that there is a tendency for recoveries to be incomplete and for the disease to be followed by a protracted period of convalescence. In Vienna and in the other large cities there is usually an increase of morbidity observed in the fall, especially as regards diphtheria, measles shows more commonly a retrogression. Investigations are now being undertaken by the municipal school physicians. Of the infectious diseases, only influenza and sore throat were prevalent to any great extent in adults. The manifestations of sore throat were, however, in many cases severe and were associated with many complications, but the crisis appears to have been passed.

The Public Health in 1932

In 1932 the continuous decline of the birth rate was accentuated by the economic depression. The final figures for the general death rate, which are not yet available, will probably compare unfavorably with previous years because there were serious epidemics of diphtheria and influenza in the last quarter of the year. No such diphtheria epidemic has occurred in Czechoslovakia since the registration of this disease began in 1890. The epidemic of influenza was as extensive as that of 1927, if not more so. It broke out in December, while the epidemic of 1927 came in February.

The effect of the economic depression on the general nutrition of the population cannot be denied. Nevertheless, on the whole, serious undernutrition has not appeared, mainly because the population employed in large industries did not lose its connection with agriculture. The large industries are in big cities but the working class is recruited from the country, where the family usually remains while the father is employed in the city. The small farms owned by these families enable them to maintain a certain standard of living even though the father may lose his job. The city proletariat has been supported by an unemployment dole paid by the state. The state has also furnished large sums of money for the nutrition of school children of families of the unemployed, and consequently no serious conditions of undernutrition could be found through school medical inspection.

As for medical education, a decrease of medical students was registered at all four medical schools, yet the number of students is still so high that the medical schools cannot provide satisfactory teaching accommodations. The number of medical students showed a decrease mainly because there was a smaller number of foreigners registered. The decrease also in Czechoslovakian medical students resulted from the saturation of Czechoslovakia with medical personnel.

The number of physicians in Czechoslovakia has almost doubled since the World War. There are now almost 12,000 practicing in Czechoslovakia, that is an average of one physician to about 1,200 of population. That the physicians can make a living can be explained only by the development of medical insurance, which, since the World War, has mobilized large sums of money for medical fees, without which the absorption of great numbers of new physicians in practice would have been impossible. But this system is responsible for a dangerous situation at present. Unemployment goes hand in hand with the loss of rights for benefits from social insurance, and consequently the number of prospective patients for insurance physicians has been reduced. If the economic depression and unemployment do not end soon the physicians will feel sharply the drop in their income. This will be true especially of recent graduates.

Medical treatment for the unemployed is a problem, the profession has assumed this task willingly, and special committees on which physicians are serving generally free of charge are being organized all over the country for emergency medical relief for the unemployed.

Public hospitals continue to be in good condition with regard to equipment and finances. Special hospitals have been hit hard by the depression especially tuberculosis sanatoriums, preventoriums and convalescent homes which are chiefly maintained by insurance societies. Most of them suffer from lack of patients.

The famous watering places of Bohemia (Karlsbad, Marienbad, Franzensbad) are undergoing a profound change. These places have been built up mainly by catering to foreigners.

The depression has decreased the number who can afford to live at the spas. Radical changes in the management of the watering places have come about. The fees paid to the physicians have been reduced and living conditions are on a lower standard than in previous years. Living at the watering places of Bohemia is much cheaper than before the depression and as a result they are frequented to a larger extent by the Czechoslovakian population than before. It is estimated that the cost of a sojourn at these spas has been reduced even for foreigners by 50 per cent during the last two years.

In 1932 there were economies in public finances but no material reductions in public health activities. The dispensary service dealing with infant welfare, tuberculosis and venereal diseases did not suffer much reduction. These institutions have been supported from reserves accumulated in the time of prosperity together with a large grant from the Central Invalidity Insurance Agency. The depression has, nevertheless, affected the work in these institutions. The cause is not so much material as psychologic. The personnel realized the uncertainty of their future and the best workers began to look for positions of better stability and tenure. Psychologic uneasiness of the personnel led undoubtedly to a certain stagnation.

Czechoslovakia has survived the past year, the most difficult one in its history, without any serious damage to the health of the people.

Leaflets Placed in Periodicals

The State Institute of Public Hygiene of Prague gives out, fifteen times a year, a leaflet describing some new method which the institute is using in public health work. These leaflets are edited by the scientific directors of the institute and represent the opinion of the most qualified persons of the country. They are numbered and issued so that they can be assembled into a volume later on. The institute has a contract with Czechoslovakian medical periodicals to the effect that the leaflets shall be laid in the copies of the periodicals and sent with them to every subscriber. This practice has become popular with the medical profession because physicians find in the leaflets practical information on many topics. The leaflets deal mainly with vaccination against diphtheria, the Calmette vaccine, and the use of convalescent serum against measles. They contain also information concerning epidemics and vital statistics. These leaflets are educational for the practitioners and they are inexpensive.

Cooperative Studies on Rural Health Problems

The Public Health Service is developing a close collaboration with the health section of the League of Nations. The cooperative activities concern chiefly the province of Slovakia which is quite backward, as compared with the western part of the state, in developing sanitation. As the country is agricultural, rural problems are in the forefront. The program is mainly educational. The main assistance rendered by the League of Nations is placing at the disposal of Czechoslovakia a number of experts who will function through the State Institute of Public Hygiene in Prague. The prominent role will be taken by Dr. Andrej Štampar of Yugoslavia, who has a wide reputation as a result of his work in improving rural hygiene.

The League of Nations is cooperating with Czechoslovakia in certain studies resulting from the conference held in Geneva in 1931. Three such studies are at present being conducted in Czechoslovakia. One of them is concerned with financing public health services in the rural areas, the second deals with typhoid in rural areas. Two rural districts have been selected that are especially fitted for this study. Some interesting facts have been brought out concerning the role of typhoid carriers and the methods for their detection. It appears that water and milk, which are chiefly responsible for the outbreaks of

typhoid in large cities, are not important factors in rural areas, where carriers and flies are the main problems. New light has been thrown on the interpretation of the Widal test among the carriers of typhoid. The third study concerns the sanitation of milk and its role in the nutrition of the rural population. It is apparent that the small farmers give much more care to milking and the preservation of milk than the large producers, who become careless and try to get as much profit from their business as possible without considering sanitation. It was found that tuberculosis among cows on small farms was only about half of that on large farms. Control over the large producers has become difficult because the milk market is not well organized. Milk is being sent long distances to cities. The cooperative studies being carried out simultaneously in Hungary, Poland, Czechoslovakia, Spain and parts of France will be used as material for the second rural hygiene conference, which is being prepared by the health section of the League of Nations.

Rat Plague on Ships at Amsterdam

Mr A. Vedder publishes in the *Nederlandsch tijdschrift voor geneeskunde* a study on plague. Between 1910 and 1930, plague-infected rats were found eight times on ships in the port of Amsterdam, the last discovery being in 1920. In 1932, renewed manifestations of rat plague developed on a ship coming from the Plata River. The author, who examined the rats sent to the university laboratory, emphasized the resemblance of the plague bacillus to the bacillus of pseudotuberculosis rodentium. The two have the same morphologic characteristics, the same typical forms of colonies, and the same biochemical reactions, and in inoculations into the guinea-pig only the Otten test made differentiation possible.

Like *Bacillus pseudotuberculosis-rodentium*, the plague bacillus presents three different types of colonies. In the former there is an evident relation between the degree of virulence and the form of the colonies. The same is probably true of the plague bacillus. The virulent type (type D) is not found among the strains of plague bacillus discovered in the Netherlands, including the type isolated in the case of the ship mentioned. This no doubt explains why, in the beginning of the tests, the guinea-pigs appeared so slightly susceptible to plague infection.

Decline in Tuberculosis Mortality

In 1931 the mortality from tuberculosis had dropped in the Netherlands to 7.31 per hundred thousand inhabitants. The notification of tuberculosis is not compulsory in this country, but the highly developed system of dispensaries and of visiting nurses makes it possible to exercise close supervision over the population. Between 1921 and 1930 the mortality decreased by 50 per cent in cities of more than 100,000 inhabitants and by 35 per cent in the communes of less than 5,000 inhabitants. In females, the mortality is notably higher in the rural districts than in the cities. The reasons assigned are that poor hygienic conditions have a greater influence on the life of women than on men, and that pregnancies are more frequent in the rural districts than in the cities. These observations will tend to intensify the effort to reduce the morbidity from tuberculosis in the rural sections to a percentage at least as low as that in the cities.

Report of the Encephalitis Commission

The council on hygiene has just published a report on post-vaccinal encephalitis that brings the whole question up to date. As to the nature of the relation between vaccination and encephalitis, "the most plausible assumption is that a latent encephalitogenic virus may become active under the influence

of vaccination, or that some organism already present becomes virulent as the result of the lowered resistance of the vaccinated person."

Mutual Sick Benefit Associations in the Netherlands

Dr J. A. Berger, in a comprehensive article on mutual sick benefit associations in the Netherlands, gives an outline of the history of medical service up to 1892 and 1908 and then devotes several chapters to questions that have been in the forefront since 1908. One gets from the book an impression that the physicians have done all that they could to improve the mutual sick benefit associations. In chapter III, the question of providing medical care for patients by some form of insurance is discussed. In chapter IV, the author gives an account of the struggle for leadership in the mutual associations. He discusses also the decree of 1912 and the reaction produced throughout the country. He considers the question of the free choice of physicians. He would prefer not to see the free choice of physicians upheld in the law pertaining to mutual sick benefit associations. The author gives his opinion on the province of the mutual association and on government inspection.

International Society of Medical Hydrology

At the congress of the International Society of Medical Hydrology, held recently in Amsterdam, Dr Van Breemen spoke on physical therapy. In the Netherlands, no course of instruction in physical therapy, balneology or climatotherapy is given at any university. He said that physical therapy is not accorded the practical and scientific importance that it deserves. The congress held a joint session with the medical society for combating rheumatism. The topics discussed were "Cold as a Cause of Disease" and "The Role of Seaside Treatment." Dr Carl Habermann pointed out the functional changes brought about by a visit to the seaside. Muscular strength and respiratory capacity are increased, the percentage of hemoglobin in the blood rises, the metabolism, the oxygen intake and the retention of calcium and phosphorus are all increased. Dr Gorter recounted his experimental research on the influence of a stay at the seaside.

Withdrawal Treatment for Opium Addicts

Dr F. J. H. Noordhock Hegt presented a paper on the Modinos withdrawal treatment as applied to opium smokers. This method consists in venesection done several times and injection of the blood serum subcutaneously, with gradual diminution, at the same time, of the dose of opium. When the patient has been without opium for several days, he is subjected to the smoking test. This is regarded as positive when, after having smoked a pipe of opium, the patient is seized with vomiting, a cough due to irritation, and other symptoms. The author gave some personal observations with regard to this reaction. The better results secured by Kwa and Tan, who also employed this method, may be attributed to the closer contact that they had with the patients rather than to their better application of the method itself.

Types of Pneumococcus in the Dutch East Indies

Dr Kirchmer has an article in the *Geneeskundig tijdschrift voor Nederlandsch-Indië*, in which he gives an account of his research on the types of pneumococcus occurring in the Dutch East Indies. He found that about two thirds of all cases are caused by types I and II (42 per cent, type I, 25 per cent, type II). The remaining cases are caused by type IV. He did not find type III in pneumonia cases, but he found it in a few patients with fever without pneumonia. The author observed that pneumonia with types I and II is generally more grave than pneumonia with type IV. A number of coolies were vaccinated with a polyvalent pneumococcal vaccine. The results were encouraging but did not justify any definitive conclusion as to the value of the method.

Marriages

- CLINTON E MERSHON, Adel, Iowa, to Miss Constance Vivian Hull of Berwyn, Ill., in Rosendale, Wis., Dec 24, 1932
- LLFWELLYN W LORD to Mrs Margaret Ward Jones, both of Baltimore, at Greenwich, Conn., January 28
- JAMES L GALLAGHER, Buffalo, to Miss Marie Veronica Butler at Balboa Heights, C Z, February 21
- WILLARD M MEININGER, San Francisco, to Miss Theresa Mae Ruder of Kulm, N D, January 20
- HAROLD E MILLER, New Smyrna, Fla., to Miss Margaret Easterling of Savannah, Ga., February 9
- NOBLE MURRAY EBERHART, Chicago, to Mrs Florence Ingram of Westmont, Ill., February 7
- DAVID LEMUEL HARRELL, JR., Suffolk, Va., to Miss Katie Mae Moore of Lynchburg, January 9
- PETER P DOERING to Miss Marjorie Dorothy Sandquist, both of Geneseo, Ill., February 10
- RAYMOND HASBROUCK SHRADY to Miss Janet Seed, both of New York, February 18
- OLIVER E VAN ALYEA, Chicago, to Miss Elizabeth Cameron of Milwaukee, February 11

Deaths

- Walter Ellis Sistrunk, Jr. ☉ Dallas Texas, Medical Department of Tulane University of Louisiana, New Orleans, 1906, member of the American Surgical Association, Southern Surgical Association and the Society of Clinical Surgery, fellow of the American College of Surgeons, formerly professor of clinical surgery, Baylor University College of Medicine, in 1911 entered the Mayo Clinic, Rochester, Minn., as an assistant in pathology, in 1912 was appointed first assistant in surgery, in 1914 assistant surgeon, and in 1916 attending surgeon and head of a section of general surgery, at one time associate professor of surgery of the University of Minnesota Graduate School of Medicine, Rochester, Minn., assistant professor of operative gynecology of the cadaver, New Orleans Polyclinic, 1906-1909, surgeon to the Parkland Hospital, aged 52, was found dead, March 6, of poison, in a hotel at New Orleans
- George David Stewart ☉ New York, Bellevue Hospital Medical College, New York 1889 member of the House of Delegates of the American Medical Association in 1919, professor of surgery, University and Bellevue Hospital Medical College, member of the American Surgical Association and the Associated Anesthetists of the United States and Canada fellow and past president of the American College of Surgeons past president of the New York Academy of Medicine, formerly member of the State Board of Social Welfare president of the medical board and visiting surgeon to St Vincent's Hospital consulting surgeon to the Englewood (N J) Hospital, St Mary's Hospital Orange, N J, United Hospital Port Chester South Side Hospital Bayshore St Joseph's Hospital, Yonkers, and the Bellevue Hospital, New York, aged 70, died March 9, of uremia
- David Bushrod James, Philadelphia Hahnemann Medical College and Hospital of Philadelphia, 1896, assistant in pathology and histology in 1898 demonstrator of gynecology pathology and microscopy 1899 associate professor of gynecology in 1905 and since 1910 professor and head of the department of gynecology at his alma mater fellow of the American College of Surgeons gynecologist in charge of the Hahnemann Dispensary consulting gynecologist to the Allentown (Pa) State Hospital and the William McKinley Memorial Hospital Trenton N J aged 58, died, January 19, of pulmonary edema and heart disease
- Franklin Edward Murphy ☉ Kansas City Mo University of Pennsylvania School of Medicine Philadelphia 1893 professor of clinical medicine University of Kansas School of Medicine fellow of the American College of Physicians formerly member of the state board of health, past president of the Jackson County Medical Society on the staffs of the Bell Memorial Research, Wesley and General hospitals, aged 61, died February 20 of heart disease
- Albert Draper Whiting ☉ Philadelphia University of Pennsylvania School of Medicine Philadelphia 1892 associate professor of surgery Graduate School of Medicine of

the University of Pennsylvania, aged 63, on the staffs of the Southern Home for Destitute Children and Home for the Instruction of the Deaf, and the Lankenau Hospital, where he died, February 17, of sarcoma of the right shoulder

Christian Frederick Pfingsten ☉ St Louis, St Louis College of Physicians and Surgeons, 1898, associate professor of otolaryngology, St Louis University School of Medicine, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, otolaryngologist to St John's Hospital, aged 57, died, Nov 20 1932, of chronic myocarditis

Howard Pursell, Bristol, Pa Medical Department of the University of the City of New York, 1867, member of the Medical Society of the State of Pennsylvania, also a druggist, past president of the Bucks County Medical Society, Civil War veteran, for twenty years president of the board of health of Bristol, aged 85, died, January 13, of heart disease

Isaac Jarrett Jones, Little Rock, Ark, Arkansas Industrial University Medical Department, Little Rock, 1889, formerly professor of bacteriology, University of Arkansas School of Medicine, served during the World War, aged 68, died, Dec 28, 1932, in the Baptist State Hospital, of burns received when his clothing caught fire from an open gas grate

William Loomis Griswold ☉ Greenwich, Conn, College of Physicians and Surgeons in the City of New York, Medical Department of Columbia College, New York, 1885, member of the board of education, formerly health officer, at one time on the staff of the Greenwich Hospital, aged 72, died, February 24, of carcinoma of the sigmoid

Frederick C Gessner ☉ Milwaukee, Wisconsin College of Physicians and Surgeons, Milwaukee, 1901, on the staff of the Oconomowoc (Wis) Health Resort, aged 61, died suddenly, February 11, in Rochester, Minn., of bronchopneumonia, following an operation for carcinoma of the stomach

Edward Quarles, Island Creek, Md, University of Maryland School of Medicine, Baltimore, 1899, member of the Medical and Chirurgical Faculty of Maryland, on the staff of the Calvert County Hospital, Prince Frederick, aged 55, was killed, Nov 1, 1932, when struck by an automobile

Harry Kirke Read ☉ Houston Texas, University of Minnesota Medical School, Minneapolis, 1899, past president of the Texas Public Health Association, supervisor of hygiene in the city schools of Houston, for four years member of the school board, aged 68, died, Dec 8, 1932, of uremia

William Luther Hartsell ☉ Warren, Ark, Dallas (Texas) Medical College, 1903, formerly secretary of the Bradley County Medical Society, aged 60, died, February 4, in a hospital at Little Rock, of empyema of the gallbladder, acute appendicitis, myocarditis and pulmonary edema

Rhodolphus H Rice ☉ Milwaukee, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1897, member of the American Academy of Ophthalmology and Oto-Laryngology, aged 63, died, February 8, following an operation for mastoiditis

Michael John Dillon, Jr. ☉ Springfield, Mass, Baltimore Medical College 1908 member of the board of health, fellow of the American College of Surgeons, on the staffs of the Health Department Hospital and the Mercy Hospital, aged 49 died, February 11, of angina pectoris

Sam Houston Adams, Slaton, Texas, University of Louisville (Ky) School of Medicine, 1909, member of the State Medical Association of Texas aged 57, died recently in a local hospital of wounds received when he was shot by the father of a patient

James Franklin Blair ☉ Bozeman, Mont, University of Vermont College of Medicine Burlington, 1892 fellow of the American College of Surgeons, on the staff of the Bozeman Deaconess Hospital, aged 64, died, February 6, of cerebral hemorrhage

Michael Henry Cleary, Galena, Ill Pulte Medical College Homeopathic Cincinnati, 1878, also a lawyer, formerly member of the state legislature member of the board of education aged 79 died February 2, of carcinoma of the stomach

Neldon Mason Weigle, St Louis, State University of Iowa College of Medicine Iowa City, 1932 intern at St Louis City Hospital aged 25 died January 7 of acute glomerular nephritis acute maxillary sinusitis and otitis media

Robert Frederick Hutcheson, Cedarhurst N Y, Bellevue Hospital Medical College New York 1893 member of the Medical Society of the State of New York for many years health officer of Cedarhurst aged 61, died February 18

Henry Clay Beckett, Chase City Va Vanderbilt University School of Medicine Nashville Tenn, 1884, University

of Nashville (Tenn.) Medical Department, 1885, member of the Medical Society of Virginia, aged 81, died, January 11

Daniel Francis Sullivan, West Hartford, Conn., Niagara University Medical Department, 1891, formerly member of the board of health of Hartford, for many years on the staff of St. Francis Hospital, Hartford, aged 65, died, February 5

Lyman Ross Orton, Wilmington, Mass., Boston University School of Medicine, 1927, member of the Massachusetts Medical Society, school physician and agent of the board of health, aged 33, died, January 13, of heart disease

Clarence Jennings Miner, Brooklyn, University of Minnesota Medical School, Minneapolis, 1891, served during the World War, aged 68, died, February 20, in St. Luke's Hospital, New York, of carcinoma of the stomach

John Joseph Ryle, Stamford, Conn., University of Buffalo (N. Y.) School of Medicine, 1897, chairman of the board of education, formerly health officer, aged 60, died, February 15, in the Stamford Hospital, of heart disease

Frank Harten Pratten, London, Ont., Canada, University of Toronto Faculty of Medicine, 1912, fellow of the American College of Physicians, superintendent of the Queen Alexandra Sanatorium, aged 46, died, Dec. 10, 1932

Mark Spaulding Bradley, Hartford, Conn., College of Physicians and Surgeons in the City of New York, Medical Department of Columbia University, New York, 1892, aged 65, died, February 5, of heart disease

Alexander Leon Brown, Chicago, University of Illinois College of Medicine, Chicago, 1930, aged 26, died, February 22, of acute cholecystitis with stones in the common duct and postoperative intestinal obstruction

James Wattie Fennell, Mount Hope, Ala., Birmingham Medical College, 1901, member of the Medical Association of the State of Alabama, aged 58, died, February 17, of chronic nephritis and myocarditis

Charles Sylvester Bentley, Plattsburg, N. Y., Columbia University College of Physicians and Surgeons, New York, 1896, veteran of the Spanish-American War, aged 61, died, January 29, of lymphoblastoma

James Edward Pennington, Esom Hill, Ga., University of Georgia Medical Department, Augusta, 1888, member of the Medical Association of Georgia, aged 73, died, February 13, in a hospital at Cedartown

Carroll C. Conant, Weiser, Idaho, Detroit College of Medicine, 1907, served during the World War, aged 46, died, February 17, in the Letterman General Hospital, San Francisco, of pulmonary edema

William H. Craig, Upland, Calif., College of Physicians and Surgeons, Baltimore, 1886, member of the California Medical Association, aged 73, died, January 9, in Ontario, of cerebral hemorrhage

William John Scanlan, Shenandoah, Pa., Medico-Chirurgical College of Philadelphia, 1899, president of the Schuylkill County Medical Society, aged 63, died, February 3, of coronary thrombosis

Ernest Albert LeBien, McHenry, N. D., Washington University School of Medicine, St. Louis, 1904, county health officer, aged 55, died, February 5, in a hospital at Valley City, of pneumonia

Fred Albert Keppler, Dubuque, Iowa, Marquette University School of Medicine, Milwaukee, 1929, member of the Iowa State Medical Society, aged 30, died, February 2, of a ruptured appendix

Arthur Edmund Clendenan, Edmonton, Alta., Canada, University of Toronto Faculty of Medicine, 1891, first deputy minister of health of Alberta, aged 64, died, January 24, of pneumonia

Clifford C. Leck, Austin, Minn., Homeopathic Medical Department of the University of Minnesota, Minneapolis, 1900, aged 59, died, January 26, at Excelsior Springs, Mo., of angina pectoris

George K. Beyer, Lorain, Ohio, Cleveland Medical College, Homeopathic, 1897, member of the Ohio State Medical Association, aged 67, was found dead, February 20, of heart disease

Robert C. Schroeder, St. Louis, Missouri Medical College St. Louis, 1884, for twenty years chief pharmacist at St. Luke's Hospital, aged 73, died, January 31, of pneumonia

George Harlan Johnson, Quanah, Texas (licensed, in Texas by the State Board of Medical Examiners, under the Act of 1907), Civil War Veteran, aged 89, died, January 26

Charles E. Thomson, Scranton, Pa., Bellevue Hospital Medical College, New York, 1891, medical superintendent of the Scranton Private Hospital, aged 73, died, February 13

Joseph Andrew Parks, San Diego, Calif., Vanderbilt University School of Medicine, Nashville, Tenn., 1898, aged 60, died, February 8, in La Mesa, of cerebral embolism

DuGrand D. Erway, Syracuse, N. Y., Syracuse University College of Medicine, 1883, aged 77, died, February 19, of carcinoma of the mesentery and chronic myocarditis

Benjamin Franklin Scholl, Philadelphia, Jefferson Medical College of Philadelphia, 1886, aged 72, died suddenly, January 31, of cerebral hemorrhage and arteriosclerosis

Merritt Wright Barnum, Ossining, N. Y., University of Jena, Germany, 1891, on the staff of the Ossining Hospital, aged 65, died suddenly, February 24, of heart disease

ACNE VULGARIS FOLLOWING THE TAKING OF YEAST

To the Editor—Despite the marvelous accounts of the value of yeast, written by the advertising agents of the yeast companies and supported by the foreign legion of physicians, the relative percentage of acne cases among dermatoses has not decreased. In addition, at least half of the patients suffering from acne have previously tried yeast without any benefits to themselves. But that the administration of yeast may actually induce the appearance of acne vulgaris seems to have escaped attention. The report of the following three cases of acne is of some passing interest.

CASE 1—A white man, aged 26, had suffered from a mild acne between the ages of 16 and 20 but had been entirely well for six years. Because of some indigestion he decided to take yeast, and after he had done so for three weeks there was no change in his gastro-intestinal condition and, in addition, there had developed a severe pustular acne vulgaris of the forehead and cheeks, this spontaneously disappeared two weeks after the yeast was discontinued and has not recurred for three years.

CASE 2—A white youth, aged 21, twice developed an acne vulgaris within three weeks after the administration of yeast was begun. The condition continued with increasing severity during the taking of the preparation and disappeared spontaneously within two weeks of the time that the yeast was discontinued.

CASE 3—This was in all particulars the same as in the second case reported, except that the patient was a girl.

In all three of these cases the patients were well known to me and the observations noted are correct.

H. H. HAZEN, M.D., Washington, D. C.

CAPILLARY CHANGES IN PERNICIOUS ANEMIA

To the Editor—In a typical, well defined case of pernicious anemia, one sees at a glance the oversized erythrocytes, which are present even during remissions of the disease. During a relapse, in addition, megaloblasts are perceived. Pinoy believes that these large cells are representatives of certain intravascular cells of the embryonal liver persisting in this disease to adult life. Parenthetically, some children exhibit achylia, attributed by some observers to toxemias following infectious diseases. I believe that macrocytes should be looked for in these conditions. If Pinoy is right, pernicious anemia is present from intra-uterine life until middle age without symptoms. These large cells have a diameter of 15 to 18 microns. According to Gray, the usual diameter of the capillaries is 8 microns. They are smallest in the brain and intestine and largest in the bones and skin. 20 microns. It has been noted that improvement is last manifested in the peripheral circulation. Is there a short circuit between the bone marrow and skin where the big cells following the law of least resistance because they cannot enter the small capillaries, crowd the peripheral circulation and lead one to have an erroneous idea of the blood picture as a whole? As to the hemolysis there is an increase in the fragility of the cells. True they are elastic and so are the capillaries. This elasticity decreases about the time the pernicious anemia develops and it is quite conceivable that the attrition caused by the disparity between the size of the cell and the caliber of the capillaries, together with the added fragility of the cell wall may cause it to rupture with escape of the hemoglobin into the plasma. I am aware that the hemolysis has been attributed to an increase in the permeability of the cell wall. This would simply show that the increased tension due to the disparity caused the contents to be extruded

and rendered more vulnerable the cell wall. Have any studies been made of the caliber of capillaries in pernicious anemia? Perhaps if the macrocytic erythrocytes are present from birth the capillaries would possibly enlarge to accommodate them.

THOMAS I. O'DRAIN, M.D., Philadelphia

STREPTOTRICHOSIS

To the Editor—In THE JOURNAL, January 28, is a communication from Dr. Robert N. Nye of Boston in which he takes certain exceptions to the article on streptotrichosis by Dr. Mezei and myself (THE JOURNAL, Dec. 10, 1932). Some of his criticisms are well founded, others are characteristic of the recent confusion on the subject. His first contention, that fungi are widely distributed in nature and are often harmless saprophytes, no one will deny. This is true also of some of the higher bacteria. That the medical literature abounds with reports of cases of diseases in which the alleged primary etiologic factor is in many instances probably a harmless saprophyte and in others a secondary invader is hardly to the point in his discussion of our case. His comment that "the case is most interesting and its report certainly warranted" and our own close study of the clinical course of the disease picture acquit us of any suspicion along these lines.

Our study of the literature, on the lack of which Dr. Nye chides us, has convinced us that there is a symptom complex which deserves clinical recognition and which appears to be produced by a definite and specific etiologic factor, of which our case seems to be a classic example. This disease entity of late years has been called, chiefly by the clinicians, by the single generic term streptotrichosis (or streptothricosis), and common usage has seemed to stamp this as the correct nomenclature. A study of the literature as regards the botanic classification and bacteriologic characteristics, however, does not disclose the same unanimity of opinion. To cite Dr. Nye's own authority on the subject, Castellani (*Arch. Dermat. & Syph.* 16:383 [Oct.] 1927) states:

Until recently all the species of this order (*Nocardia* Toni and Trevisan, 1889) were considered to belong to one genus, i. e., *Nocardia* Toni and Trevisan, 1889 but Pinoy has made a subdivision separating certain species into another genus which he calls *Cohnistrepthothrix* Pinoy, 1911. In doing this he points out that the original discoverers of actinomycosis, namely Harz and Bollinger in 1877 and Rivolta in 1878 thought that they were dealing with one organism but when they attempted to make cultures, it became apparent that more than one organism was implicated. Thus Bostrom isolated a parasite which grew well aerobically produced a dry membrane on the surface of broth and was capable of growth at 20 C. on gelatin but which grew better on potato at 37 C. and formed chains of arthrospores.

Wolf and Israel on the other hand obtained a parasite which grew only anaerobically and was not capable of growth at ordinary European air temperature. In broth it formed small granules or scales which fell to the bottom of the tube. These cultures often contained clublike forms and the branching filaments broke up into bacillar or coccilike forms. Inoculation of gelatin cultures into the peritoneal cavity of guinea pigs produces actinomycosis. This form is commonly called *Nocardia israeli* (Kruse, 1896). Wright maintains that this organism is the true cause of actinomycosis and that *Nocardia bovis* is merely a contamination, but this is not generally accepted.

There are however two distinct organisms which can cause actinomycosis in man and oxen, viz. *Nocardia bovis* (Harz, 1877) and *Nocardia israeli* (Kruse, 1896), but the difference between them is considerable and therefore Pinoy has separated the latter and its allies from the former and has founded the new genus *Cohnistrepthothrix* Pinoy, 1911.

In a clinical discussion of fungal diseases the same author in the January, 1928 issue of the *Archives* says: "Bronchocardioidiasis is the modern term used to denote all bronchial and bronchopulmonary conditions due to fungi of the genus *Nocardia* Toni and Trevisan, and the genus *Cohnistrepthothrix* Pinoy which were previously more commonly known as *Streptothrix*, *Actinomycosis*, *Discomyces* and *Oospora*." He divides the condition into two groups, one containing fungal granules in the sputum, the actinomycosis bronchialis or pulmonalis, and the other producing no fungal granules, the pseudoactinomycosis. He also cites several cases of bronchopulmonary streptotrichosis with the production of yeastlike bodies in the sputum.

Far be it from us to clarify all these confusing statements, on which the best authorities are not in agreement. We certainly do not deny that actinomycosis is a distinct entity and is produced by a specific infectious agent that exists in the lesions and in the pus in the form of small whitish or yellowish granules the essential element of which is a branching filamentous organism. Between this distinct entity on the one hand, however, and infections due to the hyphomycetes or lower fungi, of which the sporothrix is an example, there is again a definite clinical entity caused by a micro-organism which, briefly, is characterized by branching threadlike forms, which produce fine conidia or sporelike reproductive elements. Because of the many characteristics it has in common with both its higher and its lower neighbors, and because of its ability to accentuate some of these characteristics and depress others, it is doubtless confused with its neighbors and given names resembling them. We therefore again contend that, when a clinical picture such as we have described is encountered, in which the causative organism is established to be a slender branching filament lacking the tubular structures with the double contoured walls, protoplasmic content and transverse septums of the lower hyphomycetes, and yet able to produce sporelike reproductive elements or conidia, the term streptotrichosis be designated. Its other bacteriologic characteristics described in our article, while we believe they are correct, will doubtless be more definitely established after further work along these lines.

MAURICE KOVAT, M.D., Staten Island, N. Y.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CHRONIC EDEMA OF ANKLES

To the Editor—An underweight girl, aged 12, has had edema of the ankles for two years. This is of the pitting type and is slightly painful. There are no other subjective symptoms, except asthma of three years' duration, for which the patient uses a nasal spray (patented) containing a small quantity of cocaine. Examination shows the heart, liver and kidneys normal. Biopsy and family history are negative for Milroy's disease. The stool contains *Blastocystis hominis*, which is apparently not causing irritation. The case has been considered one of endemic nutritional edema because the patient is not a vigorous eater, however, larger quantities of protein food have made no improvement. No estimate of amount of blood serum albumin has been made. What suggestion have you as to possible cause and treatment? Please omit name.

M.D., Texas

ANSWER—Edema of the extremities may result from systemic disease or from a disease process localized to the legs themselves. The commonest systemic diseases causing edema are, of course, those of the heart, kidneys or liver. These being normal, other systemic conditions to be thought of include certain nutritional abnormalities, Milroy's disease, hypothyroidism, chlorosis and other chronic anemias, angioneurotic edema, Meige's disease and certain parasitic infections.

It is possible that the patient has a nutritional edema, but the lack of response to a high protein diet suggests the need for consideration of other causes and additions to treatment. Foods rich in vitamin B might be added to the diet. There is no single pathognomonic feature about nutritional edema, and the diagnosis must be made by exclusion of other causes and from the results of treatment. Nutritional edema may occur in several deficiency states: scurvy, beriberi, and the inanition resulting from the ingestion of insufficient protein and an excess of salt and fluid. The former two deficiency diseases are associated with a variety of signs and symptoms aside from edema.

A chronic edema such as this does not suggest the angioneurotic type, and the latter is probably not caused by cocaine, though the spray might be stopped to prove this point. Milroy's disease presents a persistent hereditary edema of the legs characterized by rather sharp demarcation of the edema, frequently periodic fever and gastric upsets, and the patient generally gives a history of its occurrence in other members of his family.

But there are cases presenting all the features of Milroy's disease in which a single member of the family is involved. In Meige's disease a peculiar trophedema is present, the cause of which is unknown.

Nephritis may occur without albuminuria, but in such cases lesions in the cardiovascular system are usually found, such as hypertension, retinal changes and cardiac enlargement. Were the edema due to an Ebstein type of nephrosis there should be rather marked albuminuria. In such cases the serum-globulin ratio is often inverted. A basal metabolic rate would exclude hypothyroidism as the basis for the swelling. Edema without albuminuria is a feature of certain chronic anemias, one of which is chlorosis, in which the patient is usually anemic and the blood studies show a greater drop in hemoglobin than in the red blood cells. Edema without albuminuria may occur with certain parasitic infections in which eosinophilia is usually present. *Blastocystis hominis* is considered nonpathogenic.

The most common forms of edema from localized tissue disease arise (1) from lymphangitis, (2) with localized obesity, and (3) from venous stasis. The edema of lymphangitis is usually a brawny one, is relatively nonpitting, and is usually preceded by or associated with definite signs of cellulitis. A local deposition of fat about the ankles is frequently seen in young girls and in the early stages it may be associated with some pitting edema resulting from a combination of venous stasis and fat deposition. Frequently familial, it may later develop into a lipodystrophy about the ankles. Postural edema from venous stasis usually increases during the day and diminishes at night. Elevation of the legs for a few hours usually reduces it materially in which case treatment by supporting bandages is indicated.

SYPHILIS AND TRANSFUSION

To the Editor—Will you give me your opinion concerning the following. A man, aged 33, had a primary lesion, Feb. 5, 1930. A dark field examination was positive. The blood Wassermann reaction was 2 plus. The patient was promptly put on neoarsphenamine, two injections weekly of 0.6 Gm., for eight doses. Then he was given two injections of his methyl salicylate 4 grains (0.26 Gm.) each, and four of mercuric salicylate, 2 grains (0.13 Gm.) each. The Wassermann reaction after this course was three plus. No rest period was permitted and the patient received, within the following two years, thirty-two injections of neoarsphenamine, each of 0.6 Gm., fifty-two of mercuric salicylate, each injection 2 grains, and sixty-three injections of sodium bismuth thioglycollate. During this interval the patient showed no evidences of mercurialism or bismuthism. The blood Wassermann reaction at the end of these treatments was negative. At the same time at which this blood Wassermann test was taken, three samples of spinal fluid were tested. Two samples were sent to the local board of health laboratory and one was sent to a private laboratory, conducted by a reliable pathologist. The board of health laboratory reported a four plus Wassermann reaction for each of their specimens. The private pathologist reported a negative Kahn and a negative colloidal gold test. What is your opinion concerning this four plus spinal fluid test following all this intensive treatment which was crowded in the space of two years? The patient, clinically, gives absolutely negative results on examination. This patient is a member of the local fire department and the members of the fire department are frequently called on to give blood for transfusion at the local city hospital, which has a large general surgical service. I have advised this patient not to donate any blood, if ever called on, but to take the hospital doctor into confidence and notify him concerning his having had a syphilitic infection for which he received treatment. What is your opinion concerning any syphilitic patient who has been pronounced "cured" after receiving extreme intensive treatment so that he shows a negative blood or spinal fluid Wassermann reaction? Could he at any time offer his blood for transfusion without danger of carrying the infection to the recipient? Do you consider that this patient still has an active form of syphilis after all this treatment? I have advised further treatment, however, in view of his four plus spinal fluid. Please omit name.

M.D., New Jersey

ANSWER—A good deal of the confusion that has developed in this case results from inadequate examination of the spinal fluid by all the laboratories concerned. An accurate cell count and total protein or globulin estimation would have been helpful as a check on the positive Wassermann test. Moreover, the Wassermann test should have been reported quantitatively and not merely as positive or negative, for the quantitative gradient is sometimes of material aid in determining the validity of serologic observations. It is certainly possible for a patient to have an abnormal spinal fluid with a negative blood Wassermann reaction, even after the described intensive treatment, but it is not probable. The use of a Kahn precipitation test on the spinal fluid in place of the Wassermann test increases somewhat the difficulties of interpretation, though the record of the Kahn test in spinal fluid examination under controlled circumstances is good.

The obvious procedure in a case of this sort is a repetition of the spinal fluid examination with the sending of the fluid to a competent laboratory that will make a complete examina-

tion It is, of course, necessary that the laboratory be given a specimen on which an adequate examination can be made, i. e., fresh, and free from blood and other contaminants

With reference to the patient's eligibility for transfusion, the status of "cure" in syphilis is still too uncertain to make it advisable for any person who has ever had the disease to offer himself as a donor for transfusion except to a person known definitely to have syphilis at the time of the transfusion. Even in this case the technic should be such that there is no possibility of interchange of blood

UNUSUAL BLEEDING

To the Editor—A woman, aged 53 has had epistaxis all her life. She knows that her mother had one severe nosebleed. She has eight brothers and sisters who have never been so afflicted. Her past history is negative. There was one pregnancy at which she bled profusely. The menstrual flow lasts from five to seven days, with severe hemorrhage. Always during menstruation she has a nosebleed and also during the time between periods. She thinks that her nose bleeds more profusely during menstruation. She is now in her climacteric and has gone for six months without menstruating but she still has nosebleeds. She weighs 200 pounds (90 Kg). There are no visible changes in the nose and throat to account for his hemorrhage. Examination of the chest and abdomen is negative. The pulse rate is 90 the blood pressure 140 systolic 85 diastolic. Examination of the urine is negative. The hemoglobin is 91 per cent red blood cells number 4 580 000 white blood cells 9 550, the coagulation time is two and one half minutes. The differential count is normal. Please omit name.

M D, Wisconsin

ANSWER—In spite of the relationship between the epistaxis and the menses, this is most likely not a case of vicarious menstruation. By the latter is meant extragenital bleeding from some part of the body occurring at regular intervals that correspond with the menstrual periods. Even before the menopause, the nosebleeds were not limited to the menstrual periods but occurred at other times as well. The increase that took place during menstruation may be attributed to the greater blood supply in the nasal mucosa which occurred at that time. The red blood count and the hemoglobin determinations are practically normal, hence the loss of blood has not been severe. In most cases like the one cited, a careful examination of the nose will reveal a local cause for the bleeding. If none can be found, it may be assumed that there is some disturbance in the permeability of the nasal capillaries. A similar condition may have been present in the uterine endometrium to account for the profuse menstrual periods, although here some disturbance in the endocrine glands may have been the responsible factor. Therapy is difficult to suggest because the etiology is unknown. The coagulation time is normal but the bleeding time and the platelet count should also be determined. Since the blood pressure is not abnormally high for a woman of 53, no treatment need be directed toward its reduction. The patient's weight is excessive but this most likely has no connection with the nosebleeds. In spite of this, an effort should be made to diminish this weight and build up the patient's general condition.

PEMPHIGUS FOLIACEUS

To the Editor—A case of pemphigus has been brought to my attention in a woman aged 60. From the universal involvement of the skin and the large easily stripped scabs and flaccid blebs, a diagnosis of pemphigus foliaceus has been made. Constitutional and subjective symptoms are marked with extreme itching burning anorexia insomnia and moderate fever. The disease has been spreading for four months, involving the entire skin but not the mucous membranes. Solution of potassium arsenite (Fowler's solution) has not checked the disease and has been discontinued because of the development of edema of the feet. Quinine hydrochloride from 4 to 6 grains (0.26 to 0.4 Gm) has been given orally for about two weeks. A slight improvement in the back is shown although whether this is spontaneous or due to quinine is unknown. Is quinine intravenously indicated? The usual soothing powders and powder bed have been used externally. I have heard indirectly of a case in Buffalo which has been cured by intravenous use of a drug of unknown identity from Germany. Do you know what drug this may be? Are any other drugs than arsenic and quinine of use? Is pemphigus foliaceus capable of remission? Have any estimates been made of the percentage of fatalities? The strength and weight and courage of the patient have been maintained. Is this of favorable omen? Please withhold name.

M D Massachusetts

ANSWER—If the case is one of pemphigus foliaceus, as seems probable from the description given the prognosis is grave in any patient but particularly in a person of 60. Recovery from this form of pemphigus is rare. The absence of lesions on the mucous membranes may be taken as a ray of hope however. Quinine by mouth or intravenously, is indicated pushed to tolerance.

The Davis treatment which includes the intramuscular administration every other day of a proprietary extract prepared from blood platelets and containing thromboplastic substances

mixed with lactose, with iron cacodylate intravenously on the alternate days, may be tried. Mild foreign protein treatment, as injections intramuscularly of the patient's own blood, or injections of vaccines, may be of benefit.

Mercurochrome-220 soluble intravenously enough to cause a febrile reaction has been known to give benefit in some cases of pemphigus but is strenuous treatment and must be given with great caution to a patient of this age. The same caution applies to the use of arsphenamine or its modifications.

High rectal lavage continued over a long period has been credited with recoveries from ordinary chronic pemphigus.

The continuous bath or long and frequently repeated baths are often beneficial, keeping down the odor and soothing the patient. The length and frequency must be graduated according to the effect on the particular patient. The temperature must be kept at about 98 to 100 F, the tub protected from drafts and a careful watch maintained on the pulse. It may be necessary to have a cool pad on the forehead. When the bath is ended, the skin should be dabbed almost dry and anointed with plain ointment of rose water or wool fat thinned with petrolatum. Or the patient may be put into a bed full of talcum powder and covered with the same powder that has already been used.

The drug from Germany might be one of many. No new German drug has gained any reputation for its value in these cases. As already indicated, remissions may occur in pemphigus foliaceus once in a while and cures have been reported in a few cases. The percentage of fatalities would probably run over 99, though no statistics are available. The maintenance of strength, weight and courage and the absence of lesions of the mucous membrane are favorable, but in spite of these the prognosis is bad.

GALACTOSE TOLERANCE TESTS—CHOLESTEROL IN BLOOD IN JAUNDICE

To the Editor—1 Will you kindly give me information as to the significance of the galactose tolerance test in cases of jaundice? How is this test performed? 2 What is the value of the determination of cholesterol esters in the blood in cases of jaundice? Kindly omit name.

M D, New York.

ANSWER—1 The galactose tolerance test is a liver function test. Its significance in cases of jaundice is therefore related to the amount of injury to the liver that is associated with the jaundice in a particular case. In this connection, the large functional reserve of the liver must be remembered. It has been shown that, in dogs, 70 per cent of the liver substance can be excised, with survival of the animal and the restoration of the liver bulk in a few weeks. There is every reason to believe that the human liver has similarly large powers of recuperation. Thus it is possible to have constant slow destruction of liver substance occurring in patients, with simultaneous regeneration, so that liver function tests would not reveal any liver damage. However, in cases of acute hepatitis of whatever origin affecting all or most of the liver, or in cases in which a chronic condition has cumulatively affected a large part of the liver, the galactose tolerance test may be expected to reveal some dysfunction. It is therefore of especial value in the differential diagnosis of painless jaundice (Shay, Harry, and Schloss, Eugene. Painless Jaundice, THE JOURNAL, April 23 1932, p 1433).

The rationale of the use of galactose for a liver function test depends on the facts that it is readily absorbed from the gastrointestinal tract, it is converted into glycogen by the liver with some difficulty as compared to other sugars, it is practically not directly utilizable by other tissues than the liver, and there is hardly any kidney threshold for this substance. It has been shown that the average normal individual excretes only 0 to 3 Gm of galactose in the urine within five hours after ingesting 40 Gm. This, then, may be taken as the measure of the ability of the normal liver to handle galactose. Liver damage is supposed to be present when more than 3 Gm of galactose is excreted in the urine within five hours. Since 3 Gm is a liberal outside limit for the normal, even small amounts over that figure are considered to be abnormal.

The following is one modification of the galactose tolerance test.

After an overnight fast, the patient is given exactly 40 Gm of galactose in two glasses of water (about 500 cc). The mixture may be flavored with a few drops of lemon juice. The patient may take water but nothing else for the next five hours. During this period the urine is collected at hourly intervals, measured and mixed. A sample of the mixed urine is then analyzed for total sugar by Benedict's method and the amount of sugar in the total urine output is calculated. When there is dextrose in the urine, as in patients with diabetes,

this must be first removed by yeast fermentation from the sample to be analyzed

2 The value of the determination of cholesterol esters in the blood in cases of jaundice depends on the fact that, when taken in conjunction with the determination of the total cholesterol and bilirubin content of the blood, it affords a method of distinguishing between jaundice due to biliary obstruction and that due to parenchymatous liver disease. E Z Epstein has recently reported a comprehensive study of a large number of cases (Cholesterol of Blood Plasma in Hepatic and Biliary Diseases, *Arch Int Med* 50 203 [Aug] 1932). Briefly, in obstructive jaundice there is usually a hypercholesteremia, which roughly parallels the degree of obstruction and the bilirubinemia and returns to normal with the relief of the obstruction. The cholesterol esters rise concomitantly with the total cholesterol in about half the cases, in other cases (probably associated with more liver damage) the cholesterol esters remain normal but lag relatively behind the increased free cholesterol. In cholecystitis and cholelithiasis without obstruction, the blood cholesterol does not vary significantly.

In degenerative diseases of the liver there is usually a marked divergence between the bilirubinemia and the cholesteremia, the more pronounced the liver damage, the greater the tendency to hypocholesteremia that accompanies the hyperbilirubinemia. In these cases the cholesterol esters are even more depressed than the total cholesterol and parallel the degree of liver damage even more accurately. A rise in the cholesterol ester value in such a case may be the first indication of an improved prognosis.

BLOOD UREA NITROGEN—DEXTROSE TOLERANCE

To the Editor—1 There has been considerable discussion concerning a stand which I have taken on a small point and I wish to know what you have to say concerning it. Until recently, I sent my blood chemistry work to an approved laboratory run by an experienced technician. The reports on blood sent for urea nitrogen examinations were returned under both headings "blood urea" and "urea nitrogen," the two terms apparently used interchangeably. On questioning the technician I readily saw that she was unaware of any difference in meaning. Later, while talking with a technician formerly employed in a large laboratory in Los Angeles, I found that she also was of the opinion that the two terms covered the same thing. She also stated that requests that came in for "blood urea" or "urea nitrogen" were reported in milligrams of "blood urea nitrogen." This laboratory handles a large volume of outside work and I contend that the use of this term to cover requests for either "blood urea" or "urea nitrogen" should not be done. It is my belief that the report should be made according to the request, as the difference between the two results is a matter of multiplying the urea nitrogen figures by 2.14. I do not wish to deprecate the intelligence of physicians on the outside by suggesting that they are not capable of interpreting the report correctly. However, in view of the fact that there is this confusion among trained and state approved technicians employed solely in laboratory work, it is not impossible to see that physicians who have so little laboratory work to be done that they cannot have a laboratory of their own might forget slight technicalities. To them such a report might mean either, in one case it would be all right and in the other it would not be correct. Fortunately the patient's life does not depend on these reports, but I would appreciate knowing the opinion of others, as I seem to be making myself obnoxious. 2 Is there a typical curve for dextrose tolerance in the case of epileptic patients? 3 Please refer me to a complete study of blood sugars and sugar tolerance tests done on adults. I have been getting freak results from repeated tests on the same individual. The technique and results have been checked and seem to be working properly. Please omit name. M D, California

ANSWER—1 The normal blood urea nitrogen is between 10 and 15 mg per hundred cubic centimeters of blood, and it is this value with which most practicing physicians are familiar. It is advisable, therefore, to report a blood urea or urea nitrogen request in terms of urea nitrogen. This enables the physician to compare the urea nitrogen value with the nonprotein nitrogen more readily. It is the custom to print the normal values for comparison.

In the earlier literature there was much confusion regarding the amount of blood urea in the blood because of the use of numerous methods, and also because of the failure to distinguish between blood urea nitrogen and blood urea values.

The blood urea content is, as the correspondent states, 2.14 times the blood urea nitrogen content. Or, the urea value multiplied by 0.467 gives the urea nitrogen. The normal blood urea values are between 20 and 32, the normal nonprotein nitrogen between 25 and 40 mg per hundred cubic centimeters of blood.

2 The dextrose tolerance of epileptic patients is usually normal. Dr E P Joslin states that he has not seen a case of epilepsy in 5,091 patients with true diabetes. The coincidence of idiopathic epilepsy and true diabetes is therefore rare. An epileptic patient on a ketogenic diet, i. e., a diet in which the supply of available sugar is reduced, will show a lower blood

sugar curve, but the fasting blood sugar of epileptic patients is usually normal.

3 Blood sugar determination and sugar tolerance tests are described in any larger textbooks on diabetes and in books on laboratory methods, such as "Approved Laboratory Technic" by Kolmer and Boerner, New York, D Appleton & Co, 1931.

DESENSITIZATION IN SENSITIVITY TO PLANTS

To the Editor—I have under my care a patient who is employed here and has charge of the greenhouse. For some years he has had a dermatitis of both hands and wrists, and recently this has appeared on his face, which became painful and tender and so swollen that his eyes were closed. The flowers to which he is sensitive are primrose, poinsettia and chrysanthemum. Of course, it is easy to say that this man can find some other occupation, but I am anxious to desensitize him, if possible, to the two plants with which he is most constantly in contact, the chrysanthemum and poinsettia. Would you please advise me the best course to pursue in proceeding to desensitize this patient? What course should he be given, what dosage, and how should it be given, that is, should it be given subcutaneously or otherwise? Can you advise me where preparations can be obtained, and approximately the cost?

M D, Minnesota

ANSWER—Testing by the patch test method is advised with leaves of primrose, poinsettia and chrysanthemum and also tomato leaves, if any are grown in the greenhouse. The plants that cause eczema should give an eczematous reaction at the site of contact within a period of from twenty-four to forty-eight hours. It should last about a week.

There is no point in treating the patient with a watery extract to the plants to which he reacts, since the results would almost certainly be disappointing. Relief may be obtained by extracting the oil out of the plants to which he reacts with acetone, concentrating this to minute volume through evaporation of the acetone, and picking up the oily residue in absolute alcohol. This extract should be filtered and diluted down serially so that the lowest dilution amounts to 1 in 10,000 solution of the oil. He can again be tested with each dilution. Treatment can be given with an alcoholic extract, below that which causes a positive skin test, through weekly injections of the alcoholic extract diluted with water to such a point that the resulting mixture contains not more than 10 or 15 per cent of alcohol. The dose can be stepped up to such a point that he tolerates ordinary exposure. Even then, however, he might show dermatitis on direct contact with the plants. It would enable him to tolerate a much greater exposure than he can stand at the present time.

TREATMENT OF DISTURBANCE OF CIRCULATION

To the Editor—A woman, about 65 years of age, has a peculiar circulatory condition. The systolic blood pressure is from 210 to 270, the diastolic from 80 to 85. The heart is slow, the rate being from 30 to 35 per minute. Her digestion seems to be poor and she is nervous. The kidneys do not seem to be affected. Can anything be done and what prognosis should I give? Please omit name. M D, Nebraska

ANSWER—This patient presents many interesting possibilities. A pulse pressure of such height, namely 130 to 190, is highly suggestive of the existence of an aortic regurgitation. One must therefore carefully reexamine the patient for the presence of cardiac enlargement, which in these cases is directed downward and to the left, a visible or palpable apical thrust, a blowing diastolic murmur at the base of the heart, commonly heard best at the third left interspace near the sternal margin and transmitted down the sternum, the Duroziez murmur over the femoral artery, visible, pulsating carotid and brachial arteries, and a capillary pulse at the margins of an artificially produced hyperemic area on the forehead. A bounding, collapsing pulse should be present unless the peripheral arteries are too rigid. If some or all of these signs have been observed, the most important etiologic factors to be considered are syphilis, arteriosclerosis and rheumatism. The history and blood Wassermann or Kahn tests will be of value, and the degree of peripheral and retinal arteriosclerosis may offer a clue toward the solution of the etiology. In the absence of aortic insufficiency, high pulse pressures have been observed in instances of hypertension and arteriosclerosis and in thyrotoxicosis, but no signs pointing to the latter are mentioned. The slow pulse rate of 30 to 35 is indicative of complete heart block, the ventricles and auricles having their own independent rhythm, the pathologic disturbance is in the conducting bundle of His and may be due to scarring secondary to coronary sclerosis or to gummatous changes. Such a high systolic pressure, even in the presence of aortic insufficiency, warrants a diagnosis of hypertension, which is probably associated with renal arteriosclerosis or so-called nephrosclerosis (primary contracted kidneys). From a prognostic standpoint it is important to carry out studies on the renal function, for which the

phenolsulphonphthalein test, concentration and dilution test and blood urea or nonprotein nitrogen are adequate. Finally, it is to be recalled that there are instances of complete heart block in which, because of the long diastolic phase and more complete filling of the heart, the systolic pressure may reach as high as 200 and over and the diastolic pressure remain normal or subnormal. The indigestion may be due to a mild degree of heart failure, corroborative evidence of which would be a palpably enlarged tender liver.

The prognosis is difficult to conjecture but, in the face of good renal function, is dependent on the integrity of the myocardium. Coronary thrombosis in particular is to be feared. The therapy consists of rest for one or two hours after meals and the avoidance of overexertion, excessive stimulation and fatigue. Only light exercise, such as short walks, may be permitted. Potassium iodide, 0.3 Gm (5 grains) and sodium bromide, 0.65 Gm (10 grains) three times daily are useful adjuvants. In the presence of Adams-Stokes syndrome, epinephrine for the acute phase and ephedrine sulphate, 0.024 Gm (three-eighths grain), three times daily as a prophylactic measure are of distinct efficacy. Tincture of digitalis may be given in doses of from 0.6 to 1 cc (10 to 15 minims) three times daily for cardiac failure, if present.

EFFECTS OF EPINEPHRINE ON BLOOD SUGAR

To the Editor—When epinephrine is injected subcutaneously, it is known that the blood sugar rises and may even spill over into the urine. I should like to know how soon after the injection the blood sugar rises to what height it generally goes, how long the rise lasts and whether the return is rapid or slow. Kindly let me have as many references as possible with regard to this subject and any information immediately concerned with the questions I have asked.

ISAAC APPERMAN, M.D., New York.

ANSWER—There are surprisingly few references in the recent literature to the characteristics of the blood sugar curve after the injection of epinephrine into normal human beings. It has been shown in animals that epinephrine does not produce a hyperglycemia in the absence of the liver. The liver is therefore considered to be the source of the blood sugar, and the extent of epinephrine hyperglycemia will thus depend to a large extent on the amount of carbohydrate stored in this organ. There is also some evidence to show that part of the sugar which appears after the administration of epinephrine does not originate from glycogen stores but is newly formed from non-carbohydrate materials. Another factor that influences the hyperglycemia obtained depends on the fact that epinephrine is rather quickly destroyed by the tissues. The manner and site of injection will therefore influence the results obtained. In general, subcutaneous administration produces less acute and more prolonged effects than intravenous injection. In order to obtain comparable blood sugar curves in different normal subjects after the administration of epinephrine, one would therefore have to standardize the following factors: (1) dose of epinephrine as compared with bulk of subject, (2) carbohydrate stores of subject—previous diet, fasting period, (3) site and manner of administration of epinephrine, (4) psychic factors. Hyperglycemia may follow violent emotion or pain.

The glycogenolytic effects of epinephrine following its subcutaneous injection have been observed chiefly in lower animals, particularly the rabbit. In this animal the attendant hyperglycemia has led to a severe glycosuria (as high as 8 per cent). Following the injection of 1 mg, the blood sugar elevation was distinct at the end of one hour and had returned to its normal value at the seventh hour. In man, 1 mg injected subcutaneously effects a negligible elevation detectable only at the end of the first hour. If a glycosuria occurs at all, it is detected during the second or third hour and lasts, perhaps, two hours more. In a composite curve (four experiments on rabbits) the blood sugar elevation reached nearly 0.4 per cent at the end of the second hour, with a slow return to normal. In man, a similar dosage raised the blood sugar only from approximately 0.1 per cent to 0.15 per cent. An excellent discussion, replete with bibliographic references appears in the *Handbuch der experimentellen Pharmakologie* by A. Heffter, volume II, second part (Adrenalin und Adrenalinverwandte Substanzen by P. Trudelnburg 1924 p 124).

We have been unable to find data on epinephrine hyperglycemia in normal human beings when all the factors cited were controlled. The data that are available however indicate that following the subcutaneous injection of from 0.75 to 1 cc of 1:1000 epinephrine hydrochloride into normal adult human beings the blood sugar begins to rise almost immediately and the hyperglycemia is definite within ten minutes and reaches its height in between one and two hours. The blood sugar falls to its original level within one or two hours after the peak of the curve and a short hypoglycemic phase may follow. The

time taken for recovery from the hyperglycemia seems particularly variable, as is also the height to which the blood sugar level ascends. Different reports give the height of the curve as from 156 to 250 mg per hundred cubic centimeters.

FISTULA OF ABDOMINAL WALL AFTER SUPRAPUBIC PROSTATECTOMY

To the Editor—A man aged 71, whose general condition is apparently good, was operated on a little over four months ago for the removal of an enlarged prostate causing acute obstruction. At present he has no complaint excepting for a restlessness because the abdominal wound has not entirely closed, i.e., intermittently urine comes through a very small opening necessitating the frequent changing of the sterilized gauze dressing. Is this the customary experience in these cases and how long does it usually take before the opening closes permanently? Can anything be done to expedite matters? Kindly omit name.

M D, New Jersey

ANSWER—Failure of closure of the abdominal fistula may be based either on an obstruction at the vesical outlet or on complete epithelization of the fistular canal. Whether such an obstruction is of a temporary or a permanent character can definitely be decided on by cystoscopy executed through the abdominal fistula. At any rate an attempt at relieving the obstruction, thus facilitating the closure of the sinus, may be made by passing urethral sounds or inserting an indwelling catheter for a few days. The latter manipulation, of course, involves the danger of causing urethritis and epididymitis. The persistence of the fistula for four months makes a definite result of such instrumentation rather doubtful. Failure of this necessitates exposure of the fistular canal and the adjacent area of the bladder and proper suturing of the defect after the scar tissue is excised. Such an operation at the same time furnishes an opportunity to explore the vesical outlet and determine the character of a definite obstruction, if present, and permits proper surgical attention to such an obstacle.

ENLARGED THYMUS AND LARYNGEAL STRIDOR

To the Editor—Please advise me concerning the following case. A girl, aged 3 months, breast fed and weighing 13½ pounds (6 Kg) is of good nutrition and appears well. She was brought in for 'noisy' breathing which has been noticed since birth to some extent, but has been more marked for the last month. While the infant has vomited a great deal she has made steady progress in growth and development. The stridor may be heard with ease at a distance of 10 feet, but there is no cyanosis and the baby seems quite happy and comfortable. Roentgen examination reveals a wide shadow in the upper mediastinum, which is interpreted as an unusually large thymus. Is roentgen treatment advised? In view of the widespread confusion regarding the thymus gland, what attitude is the profession to take regarding such cases and inducing parents to feel secure without treating them? Is there no such thing as thymus death? Please omit name.

M D, California

ANSWER—During the last two years there has been a rather abrupt change in the attitude of writers regarding conditions relative to enlargement of the thymus gland in infants. It seems possible that for several years a large number of infants have been given x-ray exposures to reduce the size of a thymus that was not causing symptoms or that would have caused no further symptoms if the x-rays had not been used. Admitting that the exact mechanics of the production of symptoms and the cause of thymic disturbances are still unexplained, it seems possible that enlargement of the thymus and the resulting symptoms may not be the same in all sections of the country. It would seem conservative to venture the statement that the demonstration of the function of the thymus gland will be followed by a less extreme attitude than either the former overemphasis or the more recent tendency to disregard simple enlargement of the thymus gland.

Given an infant with noisy breathing, there are a number of conditions that must be considered as possible causative factors in addition to the thymus. Congenital laryngeal stridor is not infrequent and should certainly be considered in the case in question. This condition may safely be expected to correct itself by the second or third year. Growths of the larynx, the most common of which are papilloma, which may be single but frequently multiple, also cause noisy breathing. The direct

examination of the larynx is to be desired in these cases and undoubtedly should be done more often than at present. The laryngeal spasm of tetany is usually quite readily recognized because of the associated manifestations. As a result of the rather general and adequate antirachitic routine usually prescribed at the present time, this type of noisy breathing is being seen less often. The presence of malformations of the larynx, growths such as hemangioma, or enlarged thyroid rests are less frequently seen.

As to the thymus itself, in view of the controversy that has arisen, and the evaluation of anteroposterior plates and those taken laterally, when these show evidence of enlargement of the thymus gland and symptoms are present it seems conservative in the present state of our knowledge to recommend x-ray exposure.

IMPOTENCE WITH GLANDULAR DEFICIENCY

To the Editor—A white American farmer, aged 32 complains of impotence. This is characterized by weak erections occurring involuntarily. There is complete failure of erection when desired. The family history is negative for hereditary disease excepting that the maternal relatives all tend to obesity. He is an only child. He has had no contagious diseases. In 1918 he had influenza, recovery was prompt without complications. He has not had mumps. There is no history of venereal infection. At about the age of 20, after several years of normal libido, he had a gradual cessation of libido with an increase in weight amounting to about 30 pounds (13.6 Kg) in the course of a year. This change was not induced by any sexual shock, disappointment or other abnormality. He was married about six years ago and has one child about five years old. The marriage has no apparent effect on the condition. He has recently had treatment, probably arsenic, which had no effect. He has no discoverable physical impairment. The body symmetry is good. The height is 67 inches (170 cm) the weight about 190 pounds (86 Kg). The mouth and throat appear to be free from infection. The testicles and penis are normal in development. The prostate and seminal vesicles are not tender and show no enlargement. A urologic consultant reports a normal prostatic smear and normal posterior urethra. Blood counts, urine examination and a Kahn test give negative results. Is this a pituitary deficiency and, if not, what diagnosis and treatment can you offer? Please omit name.

M D, Illinois

ANSWER—The absence of certain laboratory tests in the description of the case makes it impossible to state whether the pituitary or thyroid or both are affected. There can be no harm, however, in prescribing for the patient 5 grain (0.3 Gm) tablets of the anterior lobe of the pituitary extract, two tablets (10 grains, or 0.65 Gm) to be taken four times a day. He may at the same time take tablets of one-fifth grain (13 mg) of thyroid extract, three times a day, and note whether there is any influence as regards the obesity. The pituitary tablets may be taken for several months without any possible danger, but while taking the thyroid the patient should be watched from time to time for unpleasant symptoms. For his weak erections, the administration of the sinusoidal faradic current is indicated. One cable is connected with a rectal electrode and the other with a wet-sponge electrode and the current is allowed to pass for about ten minutes. The rapidity of the current should be moderate and the strength should be as much as the patient can bear without any pain. These treatments may be given every four or five days. It is, of course, possible that the impotence may be primarily psychologic in its causation.

ERYTHEMA MULTIFORME

To the Editor—Will you kindly give me your opinion as to the correctness of my diagnosis of the following symptoms and, if correct, will you give me the latest opinion as to the cause and the treatment. The patient is a boy, aged 12 years, of healthy parents, three other children are healthy. The boy is underweight (70 pounds, or 32 Kg) and has had good health but is not very strong. In October, 1931, he had ulcers on the lip margin and on the inner side, apparently of herpes, they did not yield promptly yet were not taken seriously. At intervals since the ulcers have recurred but do not cause much discomfort. During the spell in October a few blebs came on the dorsal surface and the palm of the hands. In October, 1932, an ulcer came on the lower lip that has failed to respond to treatment. December 10, light red spots of varying size appeared on the hand, arms, legs and neck, also a few on the body, in the mouth and on the lips with slight itching and discomfort. Constitutional symptoms are absent or very light. In from thirty-six to forty-eight hours these spots showed some fluid of light color situated shallow in the skin with a thin layer of skin covering. After eruption there was a stinging or burning in this area. Some spots are small, others as large as a silver dollar (38 mm in diameter). Pemphigus has been diagnosed. Please omit name.

M D, Texas

ANSWER—The description suggests erythema multiforme rather than pemphigus because of the appearance of an erythema before the vesicles or bullae, the occurrence in successive attacks and the localization on the hands, arms and legs as well as in the mouth. Erythema multiforme occurs usually in a symmetrical manner, pemphigus is more apt to be asymmetrical. Erythema multiforme has been shown to have a relation to

rheumatism, purpura and erythema nodosum and is supposed to be due to showers of organisms in the blood, localizing and forming emboli in the superficial skin vessels. The attacks are usually short, clearing up spontaneously in a few weeks. The chronic ulcer of the lip in the case cited may be due to some complication, though the lesions of erythema multiforme may at times persist without known cause.

During the attack the patient should be kept at rest and given alkalis. The evolution of the lesions may be hastened by a small dose, one-fourth erythema dose, of roentgen rays. They may be concealed, if desired, by calamine lotion, 8 cc, prepared calamine, 8 Gm, and zinc oxide, 8 Gm, in solution of calcium hydroxide, and rose water to make 120 cc, dabbed on as desired. Between attacks a search should be made for infectious foci and they should be removed if possible. The heart should be examined carefully for any sign of endocarditis, and efforts to raise the patient's resistance should be made. A high vitamin, calcium rich diet, stock vaccine or a vaccine made from the intestinal flora may be used and ultraviolet radiation may be given.

SCABIES OR ECZEMATOID RINGWORM

To the Editor—There is a subacute skin disease in this community. It affects all ages, both sexes and all classes. It seems to be infectious. It begins as discrete papules, later becoming vesicles, along the extremities, and itches intensely. It spreads slowly and may even cover the body, except the scalp, palms and soles. It causes no systemic reaction except in children, and then only slight. Please tell me what to do for it.

M L STUBBLEFIELD, M D, Gorman, Texas

ANSWER—On so meager a description it is impossible to do more than consider the possibilities. The first thought is of one of the forms of itch caused by the animal parasites. Scabies is most likely, for the milder, less common forms are not seen in the winter. Scabies, however, causes lesions of the palms in young children. In tender skin the burrows can often be seen leading to a papulovesicle, just beyond which the parasite lies, and can be discovered by slicing off the skin at this point very superficially.

Ecematoid ringworm might be considered, but it is difficult to understand how it could affect so many. The fungus can be found by inverting on a slide the roof of a vesicle from the toes or fingers, treating the specimen for from one to seventy-two hours in 10 per cent sodium hydroxide solution in a moist chamber, then examining with the high dry lens.

The treatment of ringworm is perhaps most often successful with the use of Whitfield ointment, from 3 to 6 per cent of salicylic acid and from 6 to 12 per cent of benzoic acid in an ointment base, applied once a day to the lesions of the extremities, with zinc oxide ointment to the rest of the body where involved.

Impetigo hardly comes into consideration, for it seldom begins on the extremities.

INCREASING WEIGHT

To the Editor—I note in the February 4 issue of THE JOURNAL an inquiry by 'M D West Virginia' concerning the technic of increasing weight. I was somewhat surprised that the answer to the doctor's inquiry made no reference to the surest technic namely that of a rest cure with superalimentation by means of exclusive milk diet.

If physical exertion is reduced to a minimum and the patient receives a glass (8 ounces) of ordinary pasteurized milk every half hour from 7 a m to 7 p m, making 6 quarts a day, without any other food or beverage or medication or cathartics or enemas, a gain in weight will occur at the average rate of 2½ pounds a week.

If the number of pounds of weight to be gained is determined by reference to height and weight tables it is possible to estimate for the given case the length of time for which this rest cure must be instituted. For example in order to gain 20 pounds, an eight weeks rest cure should be planned for.

It would take too much space to discuss this treatment in detail but the doctor who is interested may be referred to my Manual of Psychiatry (ed 6, New York, John Wiley & Sons, Inc, 1927), pages 392 to 395.

AARON J ROSANOFF, M D, Los Angeles

CARBON DIOXIDE WITH NITROUS OXIDE OXYGEN

To the Editor—I noted in Queries and Minor Notes (THE JOURNAL, February 18 p 519) the suggestion that carbon dioxide should not be used with nitrous oxide and oxygen.

Carbon dioxide has been used in the Mayo Clinic in approximately 40,000 cases in which nitrous oxide and oxygen have been used. If sufficient oxygen is given to maintain normal metabolism, carbon dioxide not exceeding about 5 per cent in the total mixture in the breathing bag, is beneficial rather than harmful and the regulating effect of carbon dioxide on respiration may be obtained when nitrous oxide and oxygen are used without reducing the oxygen content of the mixture below that necessary for satisfactory anesthesia and oxidation. Usually carbon dioxide is added to the nitrous oxide-oxygen mixture only intermittently during anesthesia for the purpose of controlling respiration.

Book Notices

The Art of Anesthesia By Paluel J. Flagg, M.D., Visiting Anesthetist to Manhattan Eye and Ear Hospital. Fifth edition. Cloth. Price \$5. Pp. 416, with 149 illustrations. Philadelphia & London: I. B. Lippincott Company, 1932.

In the preface, the author gives recognition to the fact that the art of anesthesia is acquired by becoming familiar with the laws that govern the administration of anesthesia and by developing the ability to correlate these laws. Although a knowledge of the laws is essential, this knowledge is superseded by the ability to apply them properly. He points out that this controlling element is what constitutes the essence of the art, and that the conduct of a thousand anesthetics, instead of leading to crudeness in technic, should make one a thousand times more careful. Although he recommends that the anesthetist know the science of anesthesia, he apparently wishes in this book to consider principally the art. He also points out that ether is the best anesthetic agent available for routine use. He recommends prudence in the approach to risks, temperate enthusiasm for untried agents, and steadfastness in doing what is right in spite of opposition or reward. In the period of sixteen years since the publication of the first edition of this work, the author has not found it necessary to make changes in what he thought at that time were fundamentals in anesthesia. He has found it necessary to include only new developments. He includes a brief historical sketch of anesthesia in ancient times and presents photostatic copies of interesting documents concerning Crawford W. Long's use of ether, and references to the early use of chloroform, nitrous oxide, ethyl chloride, cocaine and procaine. An outline is presented of the degrees of general anesthesia, which is referred to in various places in the text. The remainder of the book is divided into two parts. Part I deals with general, local and spinal anesthetic agents and methods. In part II are considered the remaining factors in the administration of anesthetics.

In part I, chapter 1, the author writes of general anesthesia as the first and most important type of anesthesia. He writes masterfully and explains the proper attitude toward general anesthesia. In chapter 2 he considers the stages of anesthesia: induction, maintenance and recovery, under induction he considers excitement, rigidity and relaxation. He takes up the causes and the control of each of these stages, dealing especially with difficulties and how they may be overcome. He considers various postures and their effect on respiration and relaxation. He quotes from Connell in his explanation of the percentage, or vapor tension, of ether in the air, in the lung and in the blood during various stages and degrees of anesthesia. In chapter 3, the signs of anesthesia are considered under the five headings of respiration, color, musculature, eye and pulse. The author also reviews the various methods of artificial respiration. Chapter 4 consists of general considerations of ether anesthesia, for example, the best type of ether mask, convenient methods of handling the anesthetic, the closed method, and various types of apparatus for use in application of closed methods by both oral and nasal methods. He gives attention also to intrapharyngeal and intratracheal methods. He mentions the use of ether by rectum but is not enthusiastic about the method. Intravenous ether anesthesia is mentioned but not recommended. Chapter 5 is on ethyl chloride, which is considered briefly. Chapter 6 is devoted to chloroform, which is discussed in some detail. The author's preference, however, if chloroform is to be used, is for the C-E mixture consisting of ether three parts and chloroform two parts at the beginning of the administra-

tion, pure ether is added to the mixture as anesthesia progresses, and the content of chloroform becomes very small. The author considers this mixture safer than chloroform alone, although he gives as his reason that the addition of ether to chloroform reduces the likelihood of circulatory depression. Chapter 7 is on nitrous oxide, which is treated at length. The relevant physics and chemistry are presented, and convenient appliances that the author or others have devised for the use of this agent are explained. Chapter 8 is on nitrous oxide and oxygen, which is briefly discussed. Chapter 9 is on nitrous oxide, oxygen and ether, which appears to be a favorite combination of the author. He shows pictures of several pieces of apparatus for the use of these agents and considers the difficulties encountered in their administration and the means of obtaining good results. Chapter 10 is on ethylene and is brief, since the problems involved in the use of this agent are similar to those encountered in the use of nitrous oxide. In chapter 11 is considered local anesthesia by freezing, pressure, and intravenous injections of procaine hydrochloride. In chapter 12 is taken up local anesthesia with procaine hydrochloride for surface, infiltration and regional anesthesia. The subject is covered in five and a half pages. Chapter 13 includes general considerations of spinal anesthesia, and in chapter 14 is taken up briefly the administration of spinal anesthetics.

Part II, chapter 15, includes preliminary medication, drugs, dosage and the time of administration. Chapter 16 is devoted to the postoperative treatment of the patient, the nurse's function before and during the anesthesia, and the treatment of various conditions, such as protracted unconsciousness, and circulatory shock after anesthesia and operation. Chapter 17 presents an excellent discussion of carbon dioxide, especially from the standpoint of rebreathing. Chapter 18 is concerned with emergency anesthesia, and several ingenious devices are suggested which may be used under circumstances in which little is available to work with. Chapter 19 is concerned with anesthetists' records, and chapter 20 deals with various types of aspirators. In chapter 21 the author bares his soul and expresses the point of view of the patient in a most impressive way, this is the chapter the anesthetist should read if he reads any part of this book. Chapter 22 is given over to the selection of the anesthetic for patients of various ages and for various types of operations, for labor, and in the presence of status lymphaticus. In this chapter reference is made to synergistic anesthesia. In chapter 23 is taken up intratracheal anesthesia, with the author's well known contribution to improvement of this technic. Chapter 24 deals with the various methods of artificial respiration and includes several reports of cases which indicate the value of the author's method. In chapter 25 is taken up basal anesthetics, including the barbiturates, especially sodium amylal and tribrom-ethanol. The author is not inclined to advocate the routine use of basal anesthetics at this time.

Essentials of Pediatric Nursing By Ruth Allee Perkins R.N., B.S. Assistant Director of Nursing, Ohio State University School for Nurses. Second edition. Cloth. Price \$2.75. Pp. 407, with 61 illustrations. Philadelphia: F. A. Davis Company, 1932.

The enthusiastic reception accorded this concise treatise on pediatric nursing has warranted an augmented and enlarged edition. The original text has been added to, especially in the chapters on breast feeding, nutrition, hygiene, and normal growth and development. A section has been added on the pediatric aspects of nursing in communicable diseases, and a chapter on the nursing of children requiring orthopedic care. An excellent teaching outline is appended, which may be used as a guide for nursing courses in pediatric procedure. The material is accurate, concise and practical. For the student nurse and the graduate who intends to follow pediatric nursing as her vocation, the theoretical contents are adequate, and the practical instruction is excellent. The exact and detailed descriptions of nursing procedure contained in this volume must be the most essential part of the education of any nurse whose vocation is to be the care of sick children. She must know how to carry out the special procedures used in pediatric nursing, and this information is concisely placed in her hands. For those nurses whose profession it may be to teach pediatric nursing procedure, this volume will prove a valuable guide and aid. Adequate references are included at the end of each chapter, and the volume is well illustrated.

The Last Adam By James Gould Cozzens Cloth Price \$2 50
Pp 301 New York Harcourt Brace & Co 1933

Few American novels of recent years have shown such an actual comprehension of the life of a certain type of country doctor as has this recent selection of the Book-of-the-Month Club. The book is written almost photographically with a paucity of diction that gives the reader a sense of both suspense and action. The central character is a general practitioner in a small community, who is at the same time health officer. He is confronted with an epidemic of typhoid fever which arouses great excitement in the community and an attempt to drive the doctor out of the place that he has so long held among the people. His friends rally about him. Through it all he conducts himself with a humanness that is the particular mark of physicians of this type regardless of their competence or incompetence scientifically. In one paragraph the old doctor contrasts the medicine of the past with the medicine of today.

The real trouble was I forgot to put on a big show entitled 'The Wonders of Science.' He lifted the glass and drank thoughtfully. Funny thing Janet to see the change there. When I was first practicing they kind of thought a doctor was a medicine man. They didn't know what it was all about. He was sort of dabbling in the occult and anything he did was all right with them. They don't know any more now but they've been reading the papers and they want some of that not God knows what out of a bottle. You ought to see Verney's place. Nurses sitting around in uniform making urinalyses. Half a ton of fluoroscopic machines. Verney telling all the women to get undressed for a thorough examination. When he's through he has a four page record. Nine cases out of ten he doesn't know a thing he couldn't have found out by feeling a pulse and asking a couple of questions. Talk about the occult! But everybody thinks when he's written down so much he must know something and the women are purring like cats wondering if he didn't think they looked pretty good in the raw. That's giving them proper attention. People like the Bannings who can pay for it, are going to have proper attention or know why not.

Éléments de technique physiologique Par Jean Gautrelet directeur du laboratoire de biologie expérimentale à l'école pratique des hautes études. Paper Price 60 francs Pp 420 with 287 illustrations Paris Masson & Cie 1932

This admirable compilation of physiologic procedures should interest alike the student and the experimenter. For each experiment the author indicates the materials and instruments required and the exact procedure to be followed, and gives useful bibliographic references together with a brief discussion of the principles involved. The three main divisions deal with experiments on the dog, rabbit and frog (with a few on the cat, pigeon, turtle and quail), and in each part the author takes up, besides the usual experimental procedures on circulation, respiration, digestion and metabolism, such subjects as the measurement of chronaxia, the methods of extirpation and of perfusion of organs (isolated and in situ), and the preparation of various fistulas. The book deserves a prominent place in the library of every physiologic or pharmacologic laboratory, and the author is to be congratulated on having produced a useful and usable manual.

A Guide to Human Parasitology for Medical Practitioners By D B Blacklock MD D IH D TM Professor of Parasitology Liverpool School of Tropical Medicine the University of Liverpool and T Southwell D Sc PhD MRCS Lecturer in Helminthology School of Tropical Medicine Liverpool Cloth Price \$4 Pp 271 with 124 illustrations Baltimore Williams & Wilkins Company 1932

The authors of this work have had wide experience in the field of parasitology. The book has a twofold purpose, as a practitioners guide and as a textbook for students in tropical medicine and hygiene and in public health. The text is strictly limited to the pathogenic parasites of man and the structural features utilized are those most helpful in the immediate diagnosis of the species under discussion. This elimination of detail and the abundant diagrammatic illustrations result in a simplification and increase in usability of the book for the physician who is called on to diagnose any of the well known human animal parasites. For the less common or exceptional ones he must turn to a more encyclopedic parasitology such as that of Brumpt or a helminthology such as that of Faust. The authors have provided useful keys for identification and have presented the life cycles in the form of a vertical series of illustrations with suitable explanations which reveal at a glance the sequence of stages and the agencies and vectors involved in their spread and maintenance. There are also useful tables showing the approximate sizes of the nematodes of man together with the diagnostic features of the helminth ova and

larval stages. A tabular summary is given of the life history and distribution of the filarias of man, of the infectivity of the eggs and larvae of worms found in man, and of the geographic distribution of human helminths. There is a list of parasites whose infective stages are carried by water, in foods other than flesh, and in meat, fish, crustaceans and liver. There is also a list of parasitic diseases for which arthropods serve as vehicles or vectors of the causative spirochetes, protozoans or helminths, of fluke diseases for which snails are the vehicle, and of those for which fingers contaminated with soil or feces are the vehicles. Tables are given which show the location of infective stages of parasites and the modes of infection for each, the tissues and organs invaded by the parasites in man, the diagnostic features of the parasites, and drugs, dosages and treatments. This is a practitioner's book *par excellence*.

The Psycho Analysis of Children By Melanie Klein Authorized translation by Allx Strachey Cloth Price \$5 18s Pp 393 New York W W Norton & Company Inc 1932

Tracing back a neurosis to its origin in the individual's life history, one invariably finds its deepest roots in conflicts that arise in the first years of childhood. Melanie Klein is the first analyst to follow out in practice the procedures suggested by this observation—to deal with these conflicts at the time they arise. Applying analysis to young children means of course a modification of the technique used in the analysis of adults. One cannot ask a child 3 years old to lie down on a couch and say everything that passes through its mind. Instead, Mrs Klein encourages the child to express its emotions in playing and then interprets to it the desires, impulses and fear reactions, which reveal themselves in the play in a more or less disguised form. She thus uncovers the particular fear situation with which the child could not cope and diminishes this fear, whereupon the neurotic reactions—compulsive ideas, phobias and the like—disappear. The author presents her experiences in the present volume, illustrating the technical procedure with transparent case material and showing deep insight in the early development of the instinctive side of life, particularly the amazing amount of fear and aggression. The second part of the book, which contains the theoretical conclusions, is on a somewhat lower scientific level for two reasons: infantile fantasies are uncritically regarded as being the dynamic source of certain developments, and extremely hypothetical assumptions of Freud, as that of the death instinct, are uncritically used as "explanations" for early destructive impulses.

Zur Klinik und Analyse der psychomotorischen Störung Von Dr Otto Kauders Assistent der Universitätsklinik in Wien [Aus der psychiatrischen Universitätsklinik in Wien Vorstand Prof Dr Otto Pötzl] Sonderausgabe von Heft 64 der 'Abhandlungen aus der Neurologie Psychiatrie Psychologie und ihren Grenzgebieten' Paper Price 12 60 marks Pp 132 Berlin S Karger 1931

This monograph is an excellent phenomenologic presentation by Kauders, associate of the psychiatric clinic of the University of Vienna, who is well known in Europe as a representative of the Schilder-Goldstein school of neuropsychiatry, which emphasizes the pluralistic rather than the "either or" approach to psychiatric and neurologic phenomena. The author brings up cases of organic psychoses such as encephalitis and delirium tremens and shows how inadequate a simple neurologic approach to these problems is and how closely the psychiatric material is interwoven with the various neurologic manifestations. The book is clearly written and the various points are emphasized with force and intelligence. The point of view is probably more novel in Europe than in America, as Meyer and his students have emphasized this idea for many years.

Handbuch der Geisteskrankheiten Herausgegeben von Oswald Bumke Band IV Spezieller Teil Teil 5 Die Schizophrenie Redigiert und mit einem Vorwort versehen von K. Wilmanns Paper Price 86 marks Pp 783 with 99 illustrations Berlin Julius Springer 1932

In this section of Bumke's psychiatry the subject of schizophrenia is dealt with in the same adequate manner that has characterized the previous volumes. As each part of this series is published it looms up more and more as the most adequate writing concerning psychiatry. So many details are given in each work that a satisfactory review cannot be given. This handbook should certainly be in every medical library and in the personal library of every psychiatrist.

Medicolegal

Qualifications of Medical Expert as Affected by Locale of Practice

(Geraty v Kaufman (Conn), 162 A 33)

The defendant-physician was sued for damages for alleged negligence in treating a spiral fracture of both bones of the plaintiff's left leg. The defendant, the plaintiff claimed, applied a circular plaster cast, and, even in the face of indications of impaired circulation in the leg, did not split the cast until two days after it had been applied and did not remove it until six days after application. To prove that this treatment was improper the trial court admitted, over the defendant's objections, the testimony of several medical experts who practiced in New Haven, Connecticut, but not in New London, the community in which the plaintiff was treated by the defendant. These medical experts testified that the standard practice in the treatment of such fractures and the application of necessary casts was the same throughout the state and that that practice required the cast to be split within a few hours after application, and, if left solid for a longer period, to be split on the first sign of impairment of circulation, so as to relieve the pressure. From a judgment in favor of the plaintiff, the defendant appealed to the Supreme Court of Errors of Connecticut.

The defendant contended that the medical experts should have been permitted to testify with respect to the standard of practice only in the community where he practiced, New London. The test in this state, said the Supreme Court of Errors, in determining what constitutes reasonable care, skill and diligence, is the care, skill and diligence which physicians in the same general neighborhood and in the same general line of practice ordinarily have and exercise in like cases. The rule does not restrict the territorial limitation to the confines of the town or city in which the treatment was rendered, and under modern conditions there is perhaps less reason than formerly for such restriction. There is now no lack of opportunity for the physicians in smaller communities to keep abreast of the advances made in their profession and to be familiar with the latest methods and practices adopted. It is not unreasonable to require that they have and exercise the skill of physicians in similar localities in the same general neighborhood. It may not be sufficient if they exercise only that degree of skill possessed by other practitioners in the community in which they practice.

The question involved in this case, continued the court, is the slightly different one of whether or not a physician, in order to qualify and testify as an expert, must be familiar with the practice in the particular community in which the treatment was given, or if it is sufficient if he is acquainted with the general practice in the state. If a physician may be expected to be familiar with the methods and practices of physicians in similar localities beyond the limits of his own community, a physician may properly be permitted to testify as to the general practice in the state in the application and treatment of plaster casts. It may fairly be assumed that the standard practice in such a matter would not materially differ in the various hospitals in the state. There is no unfairness to the defendant in admitting such evidence. Indeed, a case might well arise in which it would be a practical impossibility for the plaintiff to procure expert witnesses who could testify that they know what the practice was as to the particular operation in a particular community. The judgment in favor of the plaintiff was accordingly affirmed.

Hospitals Liability for Malpractice After Person Responsible for Original Injury Has Been Released from Liability—The plaintiff was injured in an automobile accident and was taken to the defendant-hospital for treatment. Later he sued the hospital for damages, claiming that through the negligence of certain of its employees his injuries were aggravated. The hospital contended that he was barred from bringing the action because, for a consideration, he had released the person responsible for the automobile accident from all liability. A person, said the Supreme Court of Florida, division B, who has negligently injured another is liable in damages for any aggravation of those injuries due to the malpractice of a hospital or physician, if the injured person has used care in selecting the hospital or physician

The hospital or physician aggravating the original injury is jointly and severally liable with the original wrongdoer. A release from liability to one of the parties jointly or severally liable operates as a release to all other parties liable. Therefore, the release to the original wrongdoer operated to release the hospital from liability.—*Fenstone v Allison Hospital, Inc (Fla)*, 143 So 251

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Treatment of Chronic Dacryocystitis—After enumerating the advantages and disadvantages of the various methods of treating chronic dacryocystitis, Argañaraz describes a method of lacrimonasal fistulization in which, after the sac has been opened through the lower canaliculus, a trocar with cannula is pushed into the nose through the thin bony wall, the cannula being kept in place until healing is complete. The cannula is composed of a small gold tube 2 mm in diameter by approximately 2 cm in length and is provided with numerous holes. The extremity of the trocar is introduced into the interior of the lacrimal sac through the incision made in its external wall, and the delicate bony lamina of the lacrimal groove is trephined. Little pressure is necessary to overcome the feeble resistance of the bony wall. The trocar must be directed downward and inward at an angle of approximately 45 degrees. The cannula exactly fits the extremity of the trocar and on withdrawal of the latter it is left in position. The cannula must be mobilized daily to favor the formation of a fistula communicating between the lacrimal sac and the nasal cavity. This is indispensable for the success of the operation. Postoperative inflammatory reaction is rare, it is not necessary to apply any bandage, and the dacryocystitis and lacrimation from which the patient has been suffering stop immediately, provided the operation has been well performed and the cannula placed in position through the lacrimal sac.

Magnet Extraction from Vitreous—Stieren believes that in magnet extraction from the vitreous one should give the patient on admission to the hospital a full immunizing dose of tetanus antitoxin not only for its specific action but also as a foreign protein to insure systemic support for the ocular injury. The position of the foreign body being definitely known by roentgen localization a conjunctival flap is dissected as near the site of the foreign body as possible. This flap must contain all the subconjunctival tissue; the sclera should be bared. A double armed suture is passed through each end of the flap, entering from below at one end and from above at the other. This leaves a long stitch on the outside. This suture is used as a retractor so that the flap can be pulled well out of the way of the field. The knife used to incise the sclera must not be plunged into the vitreous but should penetrate only deep enough to cut through the sclera, choroid and retina. The author prefers a crucial incision as it facilitates the delivery of the foreign body adhering to the magnet. After using many kinds of knives and keratomes he finally devised a keratome that penetrates little more than 2 mm and has a double edge and an extremely sharp point. One uses only the conc tip of the hand magnet applying it over the site of

the foreign body, then making contact, and slowly moving the magnet toward the incision. One can repeat this a number of times if not successful in getting the foreign body on first contact, changing the angle of direction each time. If these maneuvers do not succeed in bringing the foreign body into the incision, one lightly presses the cone tip into the wound and makes contact, again changing the direction of the magnetic pull. The important thing is to disturb the vitreous as little as possible. Nor should a live magnet ever be approached to an eye containing a magnetic foreign body, contact should be made only when the stage is set or else the steel particle may be drawn about in the interior of the eye and cause untold damage. After the delivery of the foreign body, pure phenol is applied to the scleral incision and the double armed suture is passed beneath the opposite conjunctiva and tied on top, thus completing the toilet of the wound. From 1 to 2 cc of physiologic solution of sodium chloride is injected subconjunctivally, but not near the scleral incision, and the eye is closed. The author has rarely had detachment of the retina occur. This is due to the fact that the unwise practice of plunging a cataract knife or inserting magnet tips into the vitreous results in the formation of vitreous bands, which draw on the retina by contraction and bring about detachment in this manner. If the vitreous is examined with the slit lamp the path of a foreign body in its transit to the posterior part of the globe can be seen. It is logical to infer that drawing the foreign body again to the anterior segment of the eye with a strong magnet will create a parallel path and again injure the vitreous with the possible formation of a band which by contraction could readily detach the retina. The use of phenol in the scleral wound is of value in creating a local plastic inflammation which attaches the choroid and retina to the sclera. The best results are obtained when the foreign body has been in the eye for a short period of time.

Papilledema and Complications of Leukemia—According to Hill, the leukemias are both localized and generalized processes, attacking the eye and the brain. These processes simulate tumors and exhibit what may be termed a "malignant" tendency. As such they reproduce the picture of both hemorrhage and tumor in the cranial cavity, increasing intracranial pressure and causing papilledema. Anatomic studies of optic nerve heads and retinas in these cases regularly support the mechanical theory of choked disk and tend to disprove the inflammatory theory. They suggest the possibility that local alterations due to abnormal cellular contents in the central retinal vessels may bring about papilledema without the cooperation of an engorged vaginal sheath, in other words, the possibility of the clinical picture of papilledema without increased intracranial pressure. This hypothesis may throw light on some of the more unusual cases recorded as choked disk accompanying quite localized inflammatory processes. Even so, the alterations in the disks are due to edema and not to inflammation.

Glomerular Lesions Associated with Endocarditis—Bell found two forms of glomerulitis, namely, diffuse and embolic, in association with endocarditis. Diffuse glomerulitis

was found with the various types of endocarditis as follows: acute rheumatic, 22.2 per cent, acute primary bacterial, 28.6 per cent, subacute bacterial, 64.8 per cent, and secondary acute, 33.3 per cent. It is characterized by an increase in the number and size of the endothelial cells and often by thickening of the capillary basement membrane. The extent of capillary obstruction is usually much less than in clinical acute glomerulonephritis, but in seven instances of subacute endocarditis glomerulitis had reached the clinical level. Diffuse glomerulitis bears some relation to the intensity and duration of septicemia. Embolic, or focal, glomerulitis was found in the different forms of endocarditis as follows: acute rheumatic, 2.9 per cent, acute primary bacterial, 7.1 per cent, subacute, 52.8 per cent, and secondary acute, 5.8 per cent. In one instance there was no endocarditis. Two distinct types of embolic lesions occur—the fresh hyaline and the fibrous. The fresh hyaline lesion in its simplest form is a capillary thrombosis and all the smaller lesions are readily recognized as such. The larger lesions are composed of many thrombosed capillaries, which may be identified until the capillary walls have undergone necrosis. The hyaline lesion is not an infarct but a thrombosis and necrosis of capillaries resulting from the lodgment of bacteria. The necrotic portion of the glomerulus disintegrates and disappears. The fibrous lesion is a reaction characterized by a marked growth of the basement membranes of the capillaries. The thickened membranes obliterate the capillaries and give the glomerulus a fibrous structure. The fibers are formed entirely from basement membranes; there is no invasion by fibroblasts from without. The fibrous lesions, like the fresh hyaline, may involve one or more lobules or the entire glomerulus. It develops independently of the fresh hyaline lesions. In subacute bacterial endocarditis there were fifteen instances of severe renal insufficiency, of which five were due to embolic glomerulonephritis, seven to acute and three to chronic glomerulonephritis. The fresh, hyaline, embolic lesions develop earlier than the fibrous and may be found at any time during the course of the disease. The frequent absence of embolic lesions in typical clinical examples of subacute bacterial endocarditis has not been explained. Diffuse glomerulitis is frequently found in association with embolic lesions. Epithelial crescents frequently cause atrophy of the glomerular tufts by compression. Fibers form between the epithelial cells and convert the crescent into a dense fibrous structure. These fibers are of epithelial origin. In the glomeruli, fibers which later give the staining reactions of collagen are formed from three distinct sources—intracapillary fibers from the endothelial cells, fibers formed from thickened capillary basement membranes, and fibers formed by the epithelial cells of the crescents.

Glomerular Changes in Kidneys—By a special staining method (azocarmine) Hunter and Roberts were able to demonstrate distinct changes, interpreted as evidences of injury, in the glomerular basement membrane of kidneys damaged by uranium nitrate, mercuric chloride and potassium bichromate. The lesions in the basement membrane are purely degenerative in character, present in both acute and chronic stages of chemical nephropathies, and appear to be permanent. The renal glomerulus is more vulnerable to poisons than the tubules and fails to develop the same degree of increased resistance toward them. The authors advance the opinion that alterations in the basement membrane of the type described may play an important part in the renal disturbances induced by certain metallic salts. Fibrosis and connective tissue hyperplasia are not responsible for the appearance of the glomeruli in chronic uranium and sublimate nephropathies. The existence of other long recognized glomerular changes demonstrable with ordinary stains is affirmed. Uranium nitrate and mercuric chloride produce more histologic alterations in the glomeruli than potassium bichromate.

Study of Pathogenicity of Bacillus of Calmette-Guérin—Using a strain of BCG obtained from Calmette of the Pasteur Institute, Feldman made a deliberate attempt to increase its pathogenicity by growing subcultures of the organism on a glycerinated egg medium. Transfers were made every thirty days. From each succeeding subculture, four guinea-pigs were given injections—two intracerebrally, one subcutaneously and one intraperitoneally. The report deals with data obtained after subcultures of the organism had been grown on glycerinated egg medium for fifteen generations. Of a total of fifty-eight

guinea-pigs inoculated, lesions histologically indistinguishable from those of genuine tuberculosis occurred in the tissues of eleven, and cultures of acid-fast bacilli were obtained from each. Although the majority of the lesions occurred in animals that had been given intracerebral injections, one animal that was given an intraperitoneal injection and another given a subcutaneous injection died with lesions of a tuberculous nature. So far, attempts have failed to promote a succession of tuberculous lesions by the reinoculation into guinea-pigs of infective material from lesions. The particular strain of BCG studied is not devoid of pathogenicity for guinea-pigs, and the assertion that the organism is innocuous cannot be accepted without reservations. Subculturing the organism on glycerinated egg medium at monthly intervals for a period of fifteen generations did not markedly enhance its virulence.

Mental Phenomena Observed in Brain Tumor—Of more than 1,000 verified cases of brain tumor gathered chiefly from the literature, Henry made a digest for the purpose of determining to what extent the psychiatrist may contribute to the diagnosis and the localization. He states that neoplasms in the brain according to their location give rise to mental phenomena by which the evolution of the cephalic portion of the nervous system may be traced. In the pontomedullary region, mental phenomena are absent except for the late effects of intracranial hypertension. At times there is a disturbance of tactile sensibility, i. e., with one of the most primitive means of contact with the external world. This disturbance is manifested by the appearance of tactile hallucinations. Neoplasms affecting the base of the brain are manifested by disturbances in growth as well as by peculiar and exquisite pain reactions. They give rise to automatic laughing and crying and to crude motor phenomena in the form of rigidity, tremor, choreo-athetoid movements, assumption of fixed postures, somnolence, stupor, inability to react to the presence of food in the mouth, drooling, automatic resistiveness, mutism and in general to the manifestations of parkinsonism or catatonia. Occasionally the howling or other cries reminiscent of a lower mammalian stage in evolution are observed. Cerebellar neoplasms give rise to disorders in locomotion and the maintenance of posture and to distant pressure effects. The associated mental phenomena are about as crude as those of the pontomedullary region. The crude visual illusory and hallucinatory phenomena observed with lesions in the occipital lobes may be elicited directly through the growth of neoplasms or indirectly through increase of sub-tentorial pressure. These phenomena are less commonly observed because tumors of the occipital lobes are much less frequent. As the frontal lobes are approached, the mental phenomena observed are increasingly complex and highly elaborated. Neoplasms in the region of the fissure of Rolando disturb functions peculiar to human beings, such as reading, writing and speech. On the other hand, lesions in the temporo-sphenoidal lobes, i. e., those affecting the archipallium, give rise to gross gustatory and olfactory disorders. In other words, the response is a disturbance of primitive functions and of those senses on which lower animals depend in their external contacts. Neoplasms of the temporal lobes may be accompanied by both auditory and visual hallucinations. These are usually highly organized and resemble the visions and voices characteristic of the functional psychoses. In general it appears that lesions of the temporal lobes are prone to give rise to hallucinatory phenomena. Thus far in the progression toward the frontal region, visual hallucinations have been more com-

mon When the frontal lobes are affected, however, highly organized auditory hallucinations are more frequently observed. In this respect there is a closer approximation to the psychogenic psychoses. Neoplasms in the frontal lobes also produce gross personality changes and loss of the refinements in social contact that are characteristic of most highly civilized people. Destructive lesions cause a prompt regression to the mode of living characteristic of intracranial hypertension, but when this is the sole factor the mental phenomena tend to fluctuate with the variations in intracranial pressure. Certain mental phenomena accompany the growth of brain tumors and often precede the appearance of neurologic changes. It is essential that expert psychiatric observations be made in all cases, and in general these observations are equally important to those of the neurologist in arriving at the diagnosis and the localization of brain tumor.

Allergy and Cytologic Examination of Nasal Smears—Johnson and Goldstein's series of thirty-four cases is composed of patients who consulted a rhinologist because of symptoms referable to the nose or eyes and who from the history or examination, including the cytologic study of nasal smears, were suspected of being allergic. The ages of the patients in the series varied from 2 to 55 years. The ratio between male and female patients was about equal. The inhalants were the most common offenders. No one food stood out conspicuously in the results of testing. The most frequent symptom was obstruction to nasal breathing, due to nasal congestion, accompanied by a watery nasal discharge. Sneezing was the next in frequency. Seasonal variation was found in six cases. In the remaining cases, the symptoms were referable to the nose the year round. Exacerbations on exposure to dust were marked. Seven patients had other conditions suggestive of an allergic cause, such as eczema, asthma, migraine or spastic colitis. Contrary to the statement usually made that allergic patients show a pale and waterlogged nasal mucosa, the authors found that the color varied from a pale pink to a deeply injected red. In cases in which the symptoms had been present over a period of months, the picture of the pale and boggy mucosa was found. Polypi were found in five cases. In only a few cases was a dark frontal or maxillary sinus found on transillumination. The percentage of eosinophils found on examination of the slides varied from 5 to 100. The authors found that the count often varied within twenty-four hours. This may be due to an actual difference in the percentage of the various types of cells present or to the fact that only 100 cells were counted. The cells tend to lie in groups of from three to ten or more, and the field examined may not be a true index of the total number present.

Acute Sinusitis and Acute Otitis Media—Campbell states that a report of a rather small number of cases, in which acute sinusitis was found in practically 100 per cent of the cases of acute otitis media does not necessarily prove that all cases of otitis are secondary to sinusitis, but it at least suggests the common association of the two conditions. Furthermore, it suggests that in cases of otitis media the treatment should not be confined to the ear but should be largely directed to the elimination of the sinus infection. This can probably be done best by the frequent and thorough removal of the secretions, little stress being placed on the use of antiseptics. The results of this study further emphasize the importance of considering more seriously infection of the sinuses

as a contributing factor in gastro-intestinal conditions as well as in many other disorders of infancy. It is to be hoped that, with the realization of the frequency of sinus infection in infants and children and the direct and remote complications which ensue therefrom, more adequate prophylactic and therapeutic measures may be discovered to combat such conditions.

Treatment of Pneumonia—Avera states that in pneumonia the heart should be under control from the onset of the disease. The use of veratrum is elective. The blood pressure should be watched constantly. Digitalis should be given at the onset of the disease and continuously. It should be administered hypodermically in dosages depending on the patient's size and age. The bowels must be moved daily. Food should be given in small amounts regularly, as solid food will help to keep distention down. Good nursing is half of the treatment. Fresh, warm air is necessary. The patient should be kept quiet. Chest applications are elective but should be tried in every case unless the patient objects to their use. Antipyretics and serums are elective. Distention should be guarded against from the beginning. Drastic measures should be resorted to before allowing the patient to become distended. Dextrose and insulin should be given at the first sign of any dehydration, toxemia, or a high diacetic urine test, this being one of the most important steps in the treatment of pneumonia. The author's conclusions are based on the efficiency of dextrose and insulin treatment in approximately 100 cases of pneumonia with no fatalities.

Diagnosis and Management of Mastoiditis—According to Beilin, the roentgenographic examination of the mastoid reveals its type, the extent of its development, the cells involved and their location, the position of the sinus, as well as the character of the anterior sinus wall, and the tegmen tympani. Repeated roentgen examinations are of value in determining whether the infectious process in the mastoid is clearing up, remaining stationary or advancing. In conjunction with the clinical observations, the roentgenographic examination may indicate or contraindicate surgical intervention. The presence of perisinuous abscess or epidural abscess may often be elicited by this examination. The roentgenographic examination of the mastoid is of cardinal importance, as well as indispensable as a diagnostic aid in all cases of mastoiditis.

Treatment of Peptic Ulcer with Gastric Mucin—Fogelson states that although mucin has been used for only approximately two years in the treatment of peptic ulcer, the following conclusions are justified 1 Experimentally, gastric mucin inhibits protein digestion in vivo 2 The incidence of experimental ulcer formation in the dog can be radically reduced by adequate doses of mucin 3 One hundred and seventy intractable, complicated peptic ulcer patients were treated by the three associated Northwestern University Medical School groups, and by clinicians throughout the United States cooperating with the gastric mucin committee Over 90 per cent of these patients were relieved of all subjective symptoms in approximately one week 4 There have been two recurrences in the 110 peptic ulcer patients treated by the author during 1931

Treatment of Exophthalmic Goiter—Thompson calls attention to the fact that the form in which iodine is administered in exophthalmic goiter does not matter The effective dose of iodine is much smaller than that ordinarily employed Although iodine is important, too much dependence must not be placed on it It has reduced the number of deaths from postoperative crises but has not abolished them Therefore, everything that is known to act favorably on the disease should be used to augment the effect of iodine, e g, a high caloric diet and rest The patient should be prepared for operation in the hospital and not at home Operation should never be performed when the metabolism is rising rapidly, whether iodine is being administered or not Gain in weight and well marked reduction in basal metabolism during the administration of iodine indicate that the postoperative reaction will probably be mild One of the most important factors in determining the ability of the patient to withstand a subtotal thyroidectomy appears to be the intensity of the nervous manifestations of the disease In all doubtful cases, the operation should be done in at least two stages The extent of the thyroidectomy should be determined by the initial severity of the disease and the response of the patient to treatment and only rarely by the pulse rate during operation Auricular fibrillation in the absence of other untoward signs is not a contraindication to a subtotal thyroidectomy While the most important use of iodine is to prepare patients for operation, in a few mild cases it will control the disease indefinitely, and in many cases in which the disease persists following a subtotal thyroidectomy it may be controlled by iodine until it disappears

Treatment of Postoperative Ileus—Brown reports that three-fifths the anesthesia dose of procaine hydrochloride given intraspinally apparently relieved all symptoms of ileus in three cases that previously appeared hopeless The small dose does not cause such a great fall in blood pressure and when given below the first lumbar vertebra is fairly safe The good results from blocking the splanchnics overbalance the dangers in a severe case of postoperative ileus Intravenous injections of dextrose should be given during the spinal analgesia to counteract the fall in blood pressure

Whooping Cough—According to Rich, the evidence is insufficient to prove that the Bordet-Gengou bacillus represents the whole story of the etiology of whooping cough He shows

that influenza bacilli localize in the cilia of the respiratory tract exactly as do Bordet-Gengou bacilli They are found in this location when they act as secondary invaders, not only in pertussis but also in influenza and in measles The presence of gram-negative bacilli in the cilia in pertussis does not mean, therefore, that they are Bordet-Gengou bacilli The relation of the influenza bacillus to paroxysmal cough is discussed Mononuclear-cell infiltration of the bronchial walls, which is characteristic of interstitial pneumonia, occurs in pertussis uncomplicated by pneumonia It is pointed out that this interstitial change occurs almost exclusively in diseases in which there are strong reasons for suspecting the etiologic role of filtrable viruses (measles, influenza, pertussis), and the possibility that this lesion may be the effect of an invisible virus rather than of secondary bacterial invaders is discussed Observations bearing on the view that an invisible virus may be concerned in the etiology of pertussis are presented Cases showing intranuclear inclusion bodies in the lungs in pertussis are described, and the possibility that these may represent the effect of aspirated herpes virus is discussed Experiments that have demonstrated the existence of a filtrable virus associated with pertussis, and capable of producing respiratory catarrh, are reported in a separate communication, together with evidence relating to the role of the Bordet-Gengou bacillus

Paratyphoid-Like Fever in Children—Kuttner and Zepp describe seven cases of infection with bacilli of the hog cholera group (*Salmonella supestifer*) in children ranging from 7 months to 6 years The organisms were isolated by blood culture in every instance and fell into two groups, six of the cultures belonging to group II (monophasic) and one to group I (diphasic)

*Polymyelitis III Results of In Vitro Neutralization Tests on Serums of Both Treated and Untreated Polymyelitic Patients Beatrice F Howitt, San Francisco.—p 565

Bacterial Transformation—Compton describes two naturally occurring variants, opaque (O) and translucent (T), of an organism of the Gay-Harris group of Bacillus dysenteriae, encountered in cases of acute bacillary dysentery at Alexandria

He presents sharply defined differences between the variants in cultural, morphologic, serologic and lytic properties, with less sharply defined differences in virulence, immunizing power and susceptibility to the bactericidal action of normal serum. There appears to be no detectable difference between them in sensitiveness to salt or in biochemical properties. He discusses characteristic lenticular or fusiform bodies, which are a feature of colonies of the O variant on agar. They are thought to be of the nature of bacterial aggregates and may be a cause of the fluorescence. The usual confirmatory tests for "smoothness" and "roughness" of bacterial variants—sensitiveness to salt, clouding of broth and specific agglutination—find no application as distinguishing tests of "opaqueness" and "translucence." Instead, the differential confirmatory tests for this type of bacterial variation are internal lenticular bodies in the colony structure, fluorescence by obliquely transmitted artificial light, and phage action.

Latent Period in Passive Anaphylaxis—Lewis states that in his experiments he could not confirm the experiments of Friedberger indicating that the latent period in passive anaphylaxis could be dispensed with by using an homologous sensitizing antiserum. With the use of a guinea-pig anti-tuberculo-protein serum of high titer, guinea-pigs can be passively sensitized to a fatal anaphylactic death in not less than four hours after the injection of the sensitizing serum, the same period required for sensitization with a heterologous antiserum. The smooth muscle of the guinea-pig uterus will show anaphylactic sensitization two hours after an intravenous injection of homologous sensitizing serum. An isolated guinea-pig uterus is passively sensitized after remaining in a solution of guinea-pig anti-tuberculo-protein serum for two hours. The uterus is not sensitized after four hours in a solution of rabbit antihorse serum. The failure of the author's and of other reported experiments to show that the latent period of passive sensitization can be dispensed with, even with the use of homologous antiserum, leaves the positive results of Friedberger to be explained on some other basis.

Bacteriophage in Body Fluids and Exudates—Colvin outlines the results of his clinical investigations in fifty-five patients in regard to the importance of the various factors concerned in inhibition of bacteriophagy in body fluids. He found that variation of serum, body fluid, race of bacteriophage and bacterial strain or species introduces distinct differences in the amount of inhibition. His attempts to adapt a staphylococci or a streptococci phage to produce complete lysis in serum have been practically unsuccessful. He shows that repeated contact with serum may have a tendency to make an organism lysis-resistant and that consequently an adaptation to resist lysis develops. A study of the mechanisms of inhibition to lysis shows that serum delays multiplication of the bacteriophage but does not prevent specific fixation of the corpuscle. In the serum, the protein fraction is the main factor in inhibition of lysis, while in urine the crystalloid fraction inhibits. The observations suggest that bacteriophagy in the body is much modified as compared to test tube standards of lysis. This modification is in the direction of lessening the sterilizing capacity of the bacteriophage.

Polio-myelitis—According to Howitt's observations, of the serums from twenty-two treated patients who had recovered from polio-myelitis, six (27.2 per cent) gave positive in vitro neutralization of polio-myelitis virus, two (9 per cent) gave partial protection in the monkey, while fourteen (63.6 per cent) showed no protection. Of the serums from twenty untreated patients, eight (40 per cent) showed positive neutralization, one (5 per cent) gave partial protection, while eleven (55 per cent) failed to neutralize the virus. Antiviral substances may be present in a certain percentage of treated persons, but apparently those receiving serum treatment show less tendency to produce neutralizing substances than the untreated ones. The patients showing complete recovery after transient or only slight paralysis give more evidence of the production of a potent serum than those in whom severe paralysis develops. The author concludes that the results of her experiments may aid in explaining certain discrepancies in the reports on human convalescent serum therapy in polio-myelitis and certainly show the need for giving serum from known tested donors either recovered or naturally immune to the disease. The use of a standardized serum from immunized large animals would naturally be indicated.

Lactobacilli—According to Smith and his associates, the morphology and cultural characteristics of *Bacillus acidophilus* depend on the nature of the food supply, the pH value of the medium and the presence of small quantities of inorganic metals, such as zinc, copper and iron. Any member of the lactobacillus group may be converted into or caused to assume the morphologic and cultural characteristics of any other member. The members of the lactobacillus group may be arranged in a cycle according to their morphology and cultural characteristics. Any member of this cycle in assuming the morphology and cultural characteristics of any other member passes successively through the characterization of all intervening members in the cycle. The cycle is amenable to division into two natural parts: one is composed of members whose usual habitat is intestinal, and the other contains the nonintestinal members. In the case of adverse conditions, if the organism survives, most of the nonintestinal and practically all of the intestinal forms assume the coccoid shape. The change in morphology extends over a considerable period of time, even under the most favorable conditions. This is particularly true in the synthesis of the rod shaped bacilli. The rods pass through a definite process in their synthesis and splitting, in which an interplay of gram-negative and gram-positive forms occurs.

Blood Pressure Lowering Effect of Bismuth Subnitrate—Bruen states that arterial hypertension is mediated by increased arteriolar resistance, thereby increasing cardiac work. The abnormal arteriolar resistance is largely functional and can be reduced by dilatation. Sustained reduction of the arteriolar resistance should obviate the increased demand on the heart, defer its late secondary effects on the circulation and avoid the concomitant hypertrophy of the left ventricle and the hastened development of arteriosclerosis. Among "the pharmacologic and therapeutic characteristics essential to a substance that is to be beneficial in arterial hypertension" is that it "must decrease the arteriolar resistance without disturbing essentially the other fundamental normal characteristics of the circulation, such as the cardiac output, the velocity of the blood flow or the circulating blood volume." Bismuth subnitrate by mouth effects a reduction of blood pressure. In intensity its effect is comparable to that of the other members of the nitrite group. But the nitrite effect of the insoluble basic bismuth nitrates is more prolonged than that of the higher alkyl nitrates. A gradually increasing dosage starting from 5 grains (0.3 Gm.) can be manipulated to give the desired degree of blood pressure reduction. By repetition of the dosage at proper intervals, a temporal summation of effect as in incomplete tetanus may be obtained. The blood pressure might by this means be maintained at a relatively constant reduced level. The nitrite action is exerted almost exclusively on the arterioles. Vasomotor responses, while moderated, remain intact.

Colloidal Gold Test—Eberson and Mossman point out that their colloidal gold test for the detection of immune substances against poliomyelitis in the blood serum has shown to have a direct bearing and practical value in the following problems: 1 Study of susceptibility to this disease among the general population. 2 Selection of donors' serum for therapeutic use in poliomyelitis, especially during outbreaks. 3 Evaluation of therapeutic potency of serums from human and animal sources. 4 Prognosis during the course of poliomyelitis as related to the progressive development or complete absence of serum antibodies. 5 In vitro selection of "protected" mixtures of poliomyelitis immune serum combined with virus for purposes of active immunization.

Endoscopic Revision of Obstructing Prostate—McCarthy points out that in the endo-urethral management of prostatic obstructions there is a remote but none the less real menace of infection. Every precaution should be taken to obviate such an eventuality, including the most careful preoperative preparation, sterilization of urine, rigid operating room asepsis, shaving and other preparation as for open operation. Finally, and of utmost importance, secondary revisions should never be attempted until complete urethral convalescence has been established. This convalescence should be checked by endoscopic observation. In conclusion the author states that it is his conviction that as outlined by him there is not a single logical defect in the rationale of this method. In his hands it meets the most exacting requirements of visualization, excision and hemostasis.

Relief of Prostatic Obstruction—According to Collings, small and moderate sized prostatic obstructions may be efficiently relieved under direct vision by the high tension cutting current through the cysto-urethroscope. Because of instrumental difficulty and prolonged cystoscopic manipulation, marked enlargement had best be relieved by prostatectomy. Nine of 150 private patients operated on died (on an average of two years) after operation of heart disease, carcinoma or intercurrent infection. Five per cent of all patients required a second operation to relieve them. Eighty-five per cent of this group have been relieved of their symptoms and residual urine up to eight and one-half years after operation—an average of four years for all. The operation relieves a serious condition in an elderly patient with a minimum of danger to life. The author has not had a death due to operation.

Treatment of Benign Prostatic Obstruction—Bumpus reports that, of sixty-six patients heard from five years after transurethral treatment of benign prostatic obstruction, forty-eight expressed themselves as satisfied with the result and eighteen as dissatisfied, including six who later had to have prostatectomy. Of the twelve dissatisfied patients, two wrote that they were free of urinary symptoms but had to have sounds passed occasionally, both were operated on by cautery resection, which would seem to refute the earlier prediction that late strictures would develop in the majority of patients treated by this means. This study of 102 cases in which prostatic tissue was removed through the urethra more than five years ago

because of urinary obstruction would indicate that transurethral resection should, with improvement in technic which has occurred in the last five years, be performed with less risk, with less time spent in the hospital and consequently with less expenditure of funds, with a final functional result equal in permanence to that usually obtained after prostatectomy.

Inferior Meatal Puncture of Maxillary Sinus—Dintenfuss believes that inferior meatal puncture can be performed in almost every case of maxillary sinus and requires little previous experience. There is, however, greater discomfort and danger of air embolism, hemorrhage, shock, pain and emphysema of the soft parts following its employment. Ostial catheterization obviates these drawbacks but it cannot be used as frequently as the inferior meatal puncture because the anatomic configuration will not permit. It also demands a thorough knowledge of the anatomy of the lateral nasal wall, together with some degree of skill and experience. Nevertheless, when it can be accomplished it is performed with such apparent ease as to evoke favorable comment on the part of the patient. In the diagnosis of disease of the maxillary antrum, therefore, ostial catheterization should always be attempted before resorting to the puncture of the inferior meatus. Puncture of the inferior meatus is done in the following manner. The anterior end of the inferior turbinate, and especially that portion of the lateral nasal wall beneath, is painted with a 10 per cent solution of cocaine and epinephrine. A straight needle of the Lichtwitz type is introduced beneath the inferior turbinate until it is about half-way back, then the point is elevated by depressing the hand until it reaches the attachment of the turbinate with the lateral wall of the nose. The needle point is pushed in a direction toward the posterior part of the eyeball of the same side. A sudden penetration with a crackling of bone indicates that the procedure has been successfully accomplished.

Substitute for Cocaine and Procaine in Rhinology—Gatewood states that the 25 per cent solution of nupercaine has proved to be a most satisfactory agent for causing topical anesthesia prior to such operations as submucous resection, ethmoidectomy, intranasal antrotomy and turbinectomy. The 25 per cent solution of nupercaine produces prompt, effective and prolonged anesthesia without signs of local irritation or of systemic intoxication. When used in 1:1000 solution with epinephrine, nupercaine has been found fully as effective as a 1 per cent solution of procaine hydrochloride for infiltration anesthesia prior to tonsillectomy.

Nupercaine has the advantage over procaine for infiltration in that the duration of the anesthesia produced by the former far exceeds that following injection of the latter, as a consequence, the tendency for postoperative bleeding is less when nupercaine is used as the anesthetic agent. In the routine operative work in the rhinolaryngologic clinic at the Polyclinic Hospital, nupercaine has been employed in 87 submucous resections, 36 ethmoidectomies, 29 intranasal antrotomies, 41 turbinectomies and 212 tonsillectomies. The author describes his method of procedure in each of these operations.

Intravenous Injections—Marietta reviews the literature and states that intravenous injections are not recent medical conceptions. Their practical use may be dated back to the discovery of iso-agglutinins in the blood in 1901 and the anticoagulant use of sodium citrate in 1914 and 1915. Intravenous injections of all kinds are used more frequently than the rather definite indications for such procedures would require. The reactions occurring with varying degrees of frequency following intravenous injections may be reduced by carefully observing certain well defined rules in the preparation and the mode of administration. Whole blood is preferable to citrated blood for transfusion purposes, but for the inexperienced worker or one without proper assistants, citrated blood is best. Dextrose has the widest application of any intravenous medicament. The strength of the solution to be used is determined by the purpose for which it is to be given. Weak solutions are used when fluid is the main requirement, moderately strong solutions are used when nourishment is desired, and strong solutions are used for the relief of edema and increased intracranial pressure.

- *Adrenal Cortical Hormone. W W Swingle and J J Piffner Princeton N J—p 371
- Salt and Water Metabolism in Nephritis. J P Peters New Haven, Conn—p 435

Suprarenal Cortical Hormone—Swingle and Piffner used the cortical hormone in the treatment of twenty cases of Addison's disease, three of exophthalmic goiter, one of myxedema, two of diabetes, five of neurasthenia and psychoneurosis, one of myasthenia gravis, four of anorexia nervosa, one of myositis of undetermined origin and one of postural hypotension. The immediate results were excellent in fifteen of the twenty cases of Addison's disease. Five patients died. Two patients are still under treatment. Two patients have been observed over a long period and have been given what the authors believe constitutes an adequate amount of the hormone, but without satisfactory response. In the diseases other than Addison's disease, two patients with exophthalmic goiter felt considerably better subjectively, they showed evidence objectively of less stimulation and some increase in strength, with slowing of the pulse and decrease in the basal metabolic rate from 60 to 30 per cent in one case and from 55 to 28 per cent in the other. In two of the four cases of anorexia nervosa there was slight improvement, appetite developed in one case and an increased ability to take food developed in the other. Results were practically negative in the five cases of neurasthenia and psychoneurosis.

None of the other diseases were affected favorably by the cortical hormone. It is important to bear in mind that the clinical results reported by the authors were obtained by use of cortical extracts of relatively low potency. The preparations employed in all their work represented their earlier material, which assayed only 4 to 10 dog units per cubic centimeter. Their recent extracts made from whole glands assay from 40 to 80 dog units per cubic centimeter and hence are many times more potent than the early dissected cortex material used for clinical tests. The matter of dosage with this more potent extract and the daily requirements of patients with Addison's disease have not been worked out as yet. This is a clinical problem that remains to be solved. Judging from their assay experiments on dogs, the quantities of extract heretofore given patients are far greater than is necessary when this more potent preparation is used. The latter type of extract has been clinically tested in three severe cases of Addison's disease with excellent results.

Masked Mastoiditis—Williams states that masked or latent mastoiditis, because of its frequency, its insidious type of development, and its lack of the majority of the usual symptoms, is a disease that may present great difficulty in diagnosis. It would seem that the term "latent mastoiditis" can seldom be applied, for it would imply a period completely without symptoms and with no advance of the disease process. There is only one case in the series considered by the author that would apparently meet these criteria. Although the type of case considered by the author has usually been termed latent mastoiditis in the literature, the term "masked mastoiditis," which is occasionally used, seems much better and covers all those cases of mastoiditis presenting unusual difficulty in diagnosis. The principal signs and symptoms of latent or masked mastoiditis are as follows: 1 There is preceding infection of the upper part of the respiratory tract, with usually some symptoms of disease of the middle ear, separated in time from the appearance of symptoms referable to the mastoid process to a greater or lesser extent. 2 Great emphasis is placed by several authors on the general appearance of the patient, who loses weight, is weak and is without appetite. There is also an almost unique expression of apathy. 3 Fever is often present, which may be intermittent or of the continued type. Some of the patients had been treated for several months for typhoid before a sudden discharge from the ear called attention to the true pathologic process present. This mistake was made previous to the general use of the agglutination test for typhoid. 4 Lancinating pain is referred to the occiput, along the zygoma, into the neck and into the temporal region. 5 There is drooping or sagging of the posterosuperior wall of the external auditory canal. 6 A tendency is present for impairment of hearing to be pronounced because of involvement of the inner ear.

Urogenital Tuberculosis—Thomas and Kinsella point out that the successful surgical treatment of urogenital tuberculosis depends primarily on an accurate diagnosis. This may be accomplished only after repeated complete urologic examinations. Surgical treatment for any type of tuberculosis, except in an emergency, should not be undertaken until the patient has developed a sufficient defense mechanism. The surgical treatment of urogenital tuberculosis is rarely an emergency.

Surgical or medical treatment of tuberculosis should aim at the patient as a whole, not alone at the local lesion. Renal tuberculosis or other urogenital lesions are local manifestations of a constitutional disease. Nonsurgical renal tuberculosis, unilateral or bilateral, is a nonsurgical condition and should be treated intensively by medical methods. Tubercle bacilli in one specimen of urine obtained from the kidney pelvis is not in itself an indication for nephrectomy. Unilateral slightly destructive tuberculosis should be treated conservatively under careful observation. Nephrectomy is indicated only when progressive disease is present. Extensive unilateral destructive lesions should be treated by surgical methods. Bilateral destructive renal tuberculosis is not a surgical condition except to stop hemorrhage or to relieve pain and sepsis the result of an obstructed ureter. This condition is not always a hopeless one as ordinarily considered. Under careful medical management it may be compatible with life and useful work for a number of years. Genital tuberculosis is usually an infection of the prostate and epididymis and in a high percentage of patients is associated with a renal lesion. Tuberculous abscesses of the prostate occur frequently. They drain into the posterior urethra and may produce pus and tubercle bacilli in the urine. Tuberculosis of the epididymis is often an acute disease and may be cured by drainage and heliotherapy. When an operation is necessary it should be epididymectomy and not orchidectomy. Surgical treatment of tuberculosis does not cure the disease but is merely a mechanical aid in producing a clinical result. Constitutional treatment of urogenital tuberculosis is important and should supplement the surgical treatment, both before and after operation.

Myosarcoma of Rectum—Rankin and Larson sum up the characteristics of myosarcoma of the rectum as follows: 1. The lesion occurs most frequently among men in the fifth and sixth decades, only one case of a woman was found recorded in the literature. 2. The tumor is slow growing with late metastasis but with marked tendency to local recurrence. 3. The tumor occurs as a rounded circumscribed mass lying close to the internal anal sphincter and originating in the muscular tissues, later it breaks through into the rectal mucosa and then externally to the perianal tissues. 4. After involvement of the mucous membrane the lesion somewhat resembles carcinoma, but the two can usually be distinguished by careful examination. A myosarcomatous tumor possesses a broad indurated base resulting from considerable growth before the mucosa is reached. The lesion encroaches on the lumen to a greater extent than does carcinoma, resulting in symptoms of obstruction before ulceration and bleeding occur. 5. Regional lymphatic involvement is apparently rare in cases of myosarcoma, but common in the case of carcinoma, death in the former takes place from direct extension to pelvic organs, to obstruction and to local recurrences, and when the blood stream is invaded to generalized sarcomatosis. 6. In the clinical differentiation the chief conditions to be considered are carcinoma, syphilis, tuberculosis and polyp. The early involvement of the mucous membrane is carcinoma, resulting in ulceration, bleeding, infection and frequently cachexia, in contrast to that of myosarcoma, in which constipation, straining and urinary difficulties are the first symptoms. 7. Myosarcoma exhibits a marked tendency to local recurrences after excision. This was evidenced in each of four cases reported by the authors and it would seem that radical treatment by wide excision locally is warranted. Furthermore, it seems unlikely that much benefit can be derived from radiotherapy even in large doses, so that resection is, no doubt, the treatment of choice.

Sodium Amytal Anesthesia in Obstetrics—According to Swendson, the intravenous administration of comparatively small, individualized doses of sodium amytal gives more uniform and satisfactory pain relief during labor than when the drug is given orally. Oral administration of somewhat larger doses, however, because of its simpler and safer technic, should be used whenever possible, since it can be supplemented by intravenous injections of the drug if satisfactory relief from pain is not obtained. Either method of administration, when supplemented by an inhalation anesthetic, produces gratifying amnesia and safe and adequate relief from pain during most labors. Neither the oral nor the intravenous methods of administration produce deleterious effects on the infants.

Solid Double Rudimentary Uterus with Absence of Cervix and Vagina E. K. F. Ronka, Boston—p. 945

Etiology of Eczema—According to Macdonald, exogenous eczema can be diagnosed by patch tests, but the investigator will undoubtedly experience many failures. The patch test is of particular value in industrial eczema. The scratch test is valuable for the elucidation of dietetic problems in eczema. Infantile eczema is a dietetic problem. The Prausnitz-Küstner reaction proves the presence of sensitizing antibodies. Bacterial sensitization and glycosuria can cause eczema. The epidermophyton simulates eczema in the viciousness of its subjective signs. Objectively one numbs the other, but the trained eye can classify them. In doing a patch test, the supposedly offending substance is applied to a small square of damp linen. This is laid on the skin and covered with a larger square of rubber tissue, which itself in turn is finally overlaid with a still larger square of adhesive tape. The rubber tissue is necessary because adhesive tape, being a primary irritant, might confuse the reading, which is done from twenty-four to forty-eight hours later. These patches are most conveniently applied to the back. All suspected articles should be tested. It is of real value only in acute eczema. The scratch test is the application to small cutaneous abrasions of the proteins of various foods, pollens, and so on. All scratches should be equal in size. Blood should not appear. The knife should be sharp, a special type can be obtained from instrument makers. Normal skin is chosen for the tests. The response may occur in half an hour, but a six and twenty-four hour reading is desirable. Close observation and comparative readings are necessary for the correct interpretation of what constitutes a reaction. A reaction is positive not because it attains a certain size but because it is objectively more sizable than a control or other nonreaction substance. It is customary in performing these tests to scratch through a drop of tenth normal solution of sodium hydroxide that contains the protein for that test.

Atypical Hyperthyroidism—Rankin and Haines point out that the diagnosis of hyperthyroidism is comparatively easy in most cases. There are, however, many cases in which the diagnosis is difficult even when hyperthyroidism is being carefully considered. Difficulties are most commonly met in conjunction with or in distinguishing from fatigue states, essential hypertension, Parkinson's syndrome and chronic encephalitis without marked manifestations of Parkinson's syndrome. Many emergency cases of heart failure present opportunity for careful discrimination as to possible hyperthyroidism, and, if the condition is found, dramatic results from treatment are often obtained. Severe gastro-intestinal disorders with nausea and vomiting may be the chief manifestations of the crises of exophthalmic goiter. Coma may be precipitated in cases of diabetes by even mild degrees of hyperthyroidism. Hyperthyroidism complicating other surgical conditions has great significance and is almost invariably a contraindication to any operation other than for hyperthyroidism until the hyperthyroidism has been brought under control, as otherwise severe and possibly fatal postoperative reactions may occur. Mild hyperthyroidism may so increase the severity of various associated diseases that it must be universally kept in mind. In cases in which the patients are not seriously ill, perhaps the most frequent difficulties of diagnosis are met in association with fatigue states. Many patients with hyperthyroidism have neurotic tendencies. Many neurasthenic patients present evidences, both symptomatic and physiologic, which easily may be interpreted as being the phenomena associated with hyperthyroidism. The not infrequent elevation of the basal metabolic rate of nervous patients with normal thyroids has its origin in physiologic disturbances that produce in those patients physical disturbances simulating, if not identical with, some of the phenomena of hyperthyroidism. The patient who cannot attain a condition of physiologic rest sufficient to allow the metabolic rate to be normal at the time of the test is likely to be in a similar state at the time of clinical examination. In most cases the nervous phenomena of hyperthyroidism, and particularly of exophthalmic goiter, are obviously different from those resulting from anxiety, lack of assurance, and so forth, but in the mild case there may be a good deal of difficulty in the differentiation. Clinical signs may be very vague. The intoxication of hyperfunctioning adenomatous goiter, physiologically identical with the intoxication produced by ingestion of sufficient quantities of desiccated thyroid, is usually not noticed by the patient until a rather advanced stage is reached. Mild cases of exophthalmic goiter are being seen more frequently, and exophthalmos and considerable enlargement of the thyroid are being seen less frequently. Each of the last few years has brought an increasing need for more meticulous care in observation to determine the presence of hyperthyroidism. Series of tests of the basal metabolic rate instead of single tests and the determination of the effect of iodine in cases of neurosis, essential hypertension or Parkinson's syndrome in which exophthalmic goiter is suspected, are valuable aids to differential diagnosis. Hyperthyroidism should be considered in cases of cardiovascular disturbances, atypical gastro intestinal disturbances with vomiting or diarrhea and cases of diabetes with increased insulin requirements, even though other apparently sufficient causes for the disturbances may be present.

Pain in Extremities—A number of conditions in which pain in the extremity cripples an individual have been treated by Reichert by interruption of the sympathetic pathways to the affected limb. Although grateful improvement or relief of this symptom can be secured it must be borne in mind that the underlying pathologic process still exists and efforts must be made to arrest its progress. Since the dominant factor in these conditions is circulatory protection of the limb from cold must be continued even after the sympathetic block.

Selection of favorable cases is made by a preliminary paravertebral procaine hydrochloride injection of the sympathetic chain, which enables the patient to be ambulatory and to assist the physician, by endeavoring to induce pain, to judge whether permanent interruption would be beneficial. The author has obtained improvement following interruption of the sympathetic pathways in over forty cases for conditions such as Raynaud's disease, scleroderma, xeroderma, selective arthritic cases with obvious vasomotor instability, thrombo-angitis obliterans and arteriosclerotic claudication.

Plasmochin in Prevention of Malaria—Baker and Gill tested the value of plasmochin in Alabama by administering it at regular intervals to all the people in a certain area and observing the effect on the incidence of malaria during the season. They selected two rural areas for the purpose of the experiment, one was in Macon County and the other in Montgomery County. In the 1930 season every person in the demonstration areas received one tablet of plasmochin compound per week (containing 0.01 Gm of plasmochin and 0.125 Gm of quinine sulphate). In 1931 the dosage of plasmochin was increased to one tablet twice a week. The results of their experiments suggest that plasmochin compound in a dosage of from one to two tablets per week (each tablet containing 0.01 Gm of plasmochin and 0.125 Gm of quinine sulphate), when administered to all the inhabitants of a district, will materially lessen the incidence of malaria. Such a dosage is both safe and convenient. If further experience should confirm these results, it would seem that a valuable addition has been made to the present methods of malaria control, which therapeutic control may be further enhanced through scientific chemical study of the potentialities embraced in plasmochin.

Distortions of Visual Fields in Brain Tumor—According to Horrax and Putnam, intracranial tumors confined to the occipital lobes are comparatively rare, occurring in only forty instances in a series of 1,881 verified intracranial growths. In an extremely large proportion (73.6 per cent) of patients having tumors confined to or chiefly compressing the occipital lobe, fields of vision show a contralateral, homonymous hemianopsia in which the central fibers remain unaffected. This is particularly true of meningiomas situated at the posterior end of the occipital lobe. An upper quadrantal homonymous defect of the visual fields was not disclosed in any case of the series, and the authors therefore regard its occurrence as rare in strictly occipital tumors. Visual hallucinations occurred in six patients (15 per cent) before operation for tumor removal. Careful investigation of these supports the idea that complex "formed" images are not provoked by occipital tumors. The differential diagnosis between temporal and occipital tumors may be impossible without ventriculography. The high incidence of spared central fibers, together with the rarity of upper quadrantal defects in the latter, are helpful, since bisection of the macula and upper quadrantanopsia are frequent in the former. Other differential features are the relatively greater tendency to the true quadrantic form (bounded by the horizontal meridian) in defects due to temporal lobe lesions, and their greater incongruity as compared to those due to tumors of the occipital lobe.

Syphilis of Nervous System in the Sudanese—Hewer reports the results of a neurologic survey of 400 syphilitic Sudanese. Routine examination of the cerebrospinal fluid showed a high incidence of abnormality. Clinical nervous disease was present in 67.5 per cent, it consisted of gummatous or vascular lesions in most cases, and there was only one that was possibly a primary optic atrophy. In the discussion the author suggests that the absence of parasyphilitic infections is due to an acquired cell immunity, associated with an allergic state, and the occurrence of such a reaction is interpreted as a stage in the development of syphilis in the community.

Lupus Sarcoma—O'Donovan reports the case of a woman dying at the age of 59 of sarcoma cutis, in which the malignant growth appeared in a lupus scar of long duration that had been heavily treated with roentgen rays, and who for about two months before death complained of weakness, pain below the heart and shortness of breath. There was fluid in the right thoracic cavity. The fluid showed leukocytes and endothelial cells. The culture was sterile. Roentgenograms showed secondary deposits in both lungs. The author has not heretofore observed a similar case in practice or in the literature. He concludes that there is a recognized close similarity in the clinical development of occupational tar and roentgen carcinomas, experimentally both carcinomas and sarcomas have been produced in animals by the application of the same irritant,

hence, as lupus carcinoma has increased in frequency since roentgen therapy was instituted, there was an antecedent probability that sarcoma might develop under similar conditions.

Treatment of Ancylostoma Duodenale Infection—The results obtained by Biggam and Ghalioungui in a series of fifty carefully controlled cases of Ancylostoma duodenale infection by the administration of hexylresorcinol in an attempt to eradicate this infection were found to be unsatisfactory, only twenty-six patients being cured, even when repeated administrations of as much as 2 Gm doses had been employed and great care exercised in the limitation of the diet. No serious toxic symptoms were observed to occur among these cases. The difference in results obtained in the authors' series of cases compared with those of the American observers may be accounted for by the fact that in Egypt one is dealing with Ancylostoma duodenale and not Necator americanus. Hexylresorcinol can, however, be of definite value in cases of severe ancylostoma anemia in which debility is marked, if one uses it as a preliminary method of treatment with a view to diminishing the intensity of the infection and improving the condition of the patient prior to the employment of other more potent drugs.

Iron Therapy in Nervous Disorders of Anemia—Sargent treated nine patients showing varying degrees of nervous disorder following anemia by large doses of iron. After an initial period of from two to three months on 150 grains (9.75 Gm) of pills of ferrous carbonate each day, it was found advisable to continue with at least 40 grains (2.6 Gm) daily, if a relapse was to be avoided. All the patients improved in from three weeks to one month from the commencement of treatment. Six cases were classed as subacute combined degeneration, and the remaining three showed evidence of severe posterior column loss or peripheral neuritis. In five, iron either restored or maintained the blood count, thus demonstrating the existence of subacute combined degeneration and peripheral neuritis with simple achlorhydric anemia. In cases accompanying a primary anemia, in which liver treat-

ment had previously been given, substitution of iron for liver led to a fall in the blood count, but an improvement in the nervous phenomena occurred. The author reports five cases in which the degree of nervous involvement complicating the anemias bore no relation to the severity of the anemia and the nervous phenomena steadily improved if large doses of iron were given, despite a rising or falling blood count. Therefore it seems not unreasonable to surmise that the various nervous phenomena associated with alimentary disturbances may be found to fall into one large group and may respond to iron therapy. It is his intention, when possible, to put this hypothesis to the test. He has not, of course, overlooked the fact that the results obtained may not be due entirely to the large doses of iron but to some impurity in the ferrous carbonate preparation.

Chronic Glaucoma.—According to Gault, there is no such disease as simple chronic glaucoma without increased intra-ocular pressure. There is no risk of precipitating blindness if operation is undertaken in advanced cases with a field approaching closely the fixation point. No lasting benefit can be expected from miotics and general treatment alone. One may regard operation as curative, or at least one may assert that it offers a means of greatly delaying the progress of the disease in a large majority of cases and that it should be undertaken as soon as a diagnosis has been made.

Calcification of Pericardium.—Under the name protodiastolic pericardiac vibration, Lian and his associates describe a heart sound the presence of which should lead the clinician to suspect calcification of the pericardium and to practice a minute roentgenoscopic examination to confirm the suspicion. The authors have heard this sound in two cases in which a pericardiac calcification was roentgenologically determined. It is a strong, vibrating sound, much louder than the normal heart sounds, with which it constitutes a rhythm of three beats. It is produced immediately after the second sound, its maximum intensity is at the apex or at the juxtaphoid region and it is heard in the entire precordial region and up to the suprasternal fossa in auscultation of the aorta, and even in the supraclavicular region in auscultation of the subclavian artery. It is differentiated from the sound of a protodiastolic gallop by its intensity and vibration, and from the third heart sound, also a protodiastolic phenomenon, by its greater strength, vibration and constancy. The reduplicated second sound of mitral stenosis, if it is loudest in the region of the apex, may be confused with the pericardiac vibration although its vibrancy is less accentuated, and the differential diagnosis may depend on roentgenologic examination. In discussing roentgenologic diagnosis the authors say that the pericardiac calcifications are best seen in the left anterior oblique position, examination in several positions permits differentiation from pulmonary or pleural calcification, even if the cardiac pulsations have been transmitted to them.

Riforma Medica, Naples

48 1900 1938 (Dec. 10) 1932

- Serotherapy in Acute Peritonitis A. Pellegrini.—p 1914
- *High Grade Secondary Anemia Due to Mercury Poisoning Case. G. Dalla Torre.—p 1926

Diseases of Biliary Tract.—Santorsola and Gandolfi cite their experiences with the combined Meltzer-Lyon drainage and cholecystography in four groups of patients. Group I comprised eight cases of altered function of the biliary excretion with lack of B bile, corresponding to serious cholecystic, pericholecystic and adhesive lesions, with the presence of calculi in the common bile duct and in the cystic duct. In group II the Meltzer-Lyon test was not reliable because of the existence of gastroduodenal lesions. In group III (consisting of twenty patients, fourteen of whom were operated on) there was a correspondence between the Meltzer-Lyon test and the cholecystographic reports. Group IV consisted of two cases in one case the presence of a large echinococcus cyst of the liver was enough to justify an abnormal cholecystogram, in the other the walls of the gallbladder did not present considerable lesions and it was probable that the dye was collected and concentrated in the gallbladder, which, hindered by the initial inflammatory processes of the mucosa (strawberry gallbladder), could not respond to the stimulus exercised by a solution of magnesium sulphate. The authors state that the cholecystography was greatly facilitated by oral administration of the dye (tetraiodophenolphthalein) in preference to intravenous injection. They found that a gallbladder shadow, modified with a certain regularity after a normal lapse of time, signified a normal gallbladder, and that a failure to undergo change in form signified a nonfunctioning gallbladder. In the presence of the gallbladder shadow, cholecystography is still capable of revealing lesions of the gallbladder even though these do not interfere with the functional capacity of the gallbladder, in which case the degree of intensity and the uniformity of the shadow and its contours constitute the criteria. Drainage with the Meltzer-Lyon test is often

and that the twenty-four hour quantities of urine were small. This was the case also in patients in whom there was no loss of fluid by other channels (vomiting, sweating, diarrhea). From this the author concludes that oliguria is one of the most frequent symptoms of cerebral tumor, although other reports on brain tumors do not mention it. He thinks that oliguria is the result of increased cerebral pressure, because, following trepanation and pressure decrease oliguria may change even into polyuria and the thirst increases. The point of attack of the intracranial pressure is probably in the mesencephalic-hypophyseal system, and the author assumes that the oliguria of brain tumor is a disturbance in the water exchange of mesencephalic-hypophyseal origin. Edema is usually absent in this form of oliguria. The author advises that all patients presenting oligodipsia, oliguria or disturbances in the humoral-histogenic water exchange should be examined for the presence of mesencephalic-hypophyseal disturbances.

Appendicitis and Sympathetic Nervous System in Gynecology—Wiesbader maintains that in disturbances of the appendix disappearing completely after surgical treatment, although the appendix shows only slight changes, the sympathetic nervous system is involved. Changes in the vermiform appendix may lead by way of the sympathetic innervation to disturbances in the menstrual cycle which disappear again following removal of the appendix. The author made observations on fifty cases. Operative treatment was resorted to in thirty and conservative treatment in twenty. Appendicitis symptoms existed in seventeen of the thirty cases and the operation revealed only slight changes, dysmenorrhea and appendical lesions existed in seven other cases, and there were menstrual disturbances together with changes in the appendix in the remaining six. The other twenty patients received conservative treatment in the form of a spasmolytic medication. In these cases, spastic conditions in the ileocecal region and in the appendix predominated, and the author thinks that in such instances spasmolytic medicaments will give the best results.

The Meinicke Clarification Test in Cerebrospinal Fluid—According to Jehn, the Meinicke clarification test on the cerebrospinal fluid is a method that is easy to perform and consequently suitable for small laboratories, and in reliability it is hardly inferior to that of the Wassermann test. Its sensitivity is not noticeably superior to that of the Wassermann test. The author thinks that the nonspecific reactions of the Meinicke clarification test in meningitis, particularly in tuberculous meningitis, are insignificant. The test makes possible the differentiation of the form of the syphilitic disturbance of the central nervous system with small quantities of cerebrospinal fluid. The fact that only a small amount (from 0.75 to 1 cc) of fluid is required is a great advantage of the Meinicke clarification test. The author states that he gave especial attention to the outcome of the test in nonsyphilitic disorders of the central nervous system and he found that it was always negative.

Present Status of Serotherapy in Diphtheria F. von Bormann—p 118

Significance of Hemato-Encephalic Barrier—On the basis of the present status of research, Hoff assumes that the cerebral fluid is formed by the choroid plexus, the meningeal vessels and the secretions of the lymph spaces of the brain, that it is resorbed by the arachnoideal villi, by the meningeal veins and by the sheaths of the nerves, and that its formation is governed by the physical laws of dialysis and infiltration. However, these alone are not sufficient and a specific secreting mechanism cannot be entirely excluded. Pharmacologic substances that are introduced directly into the cerebral fluid pass immediately into the blood, but only a few substances pass from the cerebral fluid directly into the central nervous system. This indicates that in addition to the hematocerebral

fluid barrier there is a second barrier, which protects the brain against substances passing the hematocerebral fluid barrier, and the author states that this is the glia wall that surrounds the brain. Thus the hemato-encephalic barrier consists, in addition to the hematocerebrospinal fluid barrier, of a glia wall. In this glia wall the microglia have a selecting role, but the main decision as to whether substances are to enter the cerebral cells takes place in the cell membranes themselves. Only a small part of the nutritional substances required by the brain reaches it by way of the cerebral fluid. But although only few nutritional and pharmacologic substances reach the brain by way of the cerebral fluid, the hematocerebral barrier is penetrated by infectious agents. Most of the nutritional substances are carried from the blood by way of the microglia and the cell membrane into the cerebral cell. Consequently, if the brain is to be influenced by a pharmacologic substance, the main object should not be to break through the hematocerebral fluid barrier (which can be done only by crude and not entirely harmless means) but to penetrate the glia wall gradually and to open the cell membrane of the ganglions.

Syphilitic Thrombophlebitis—Schick reports the clinical history of a patient with thrombophlebitis of the left leg. The painful, cordlike hardening extended from the popliteal fossa to the tendo calcaneus. This phlebitis had been refractory to all therapeutic measures for nine months. The anamnesis and the seroreaction finally revealed that the condition was of a syphilitic nature. Antisyphilitic therapy cured it within a comparatively short time. The case is noteworthy because the phlebitis developed during the tertiary stage of syphilis, whereas syphilitic inflammation of the veins usually occurs during the secondary stage.

Fatal Poisoning with Neoarsphenamine in Addison's Disease—Hellfors relates the case of a woman, aged 42, who, following operative removal of an ulceration of the labia minora, developed symptoms of icterus, some of which disappeared following treatment. Because syphilis was suspected the patient was given an injection of neoarsphenamine. This was followed by a severe circulatory collapse, from which the patient died twelve hours later. The postmortem examination revealed tuberculosis of the suprarenals with complete caseation. The case is noteworthy because, in spite of the complete destruction of both suprarenals, there were no clinical signs of Addison's disease, and because of the fatal effect of the single, small (0.15 Gm) dose of neoarsphenamine. The author points out that the arsenic may have caused a breakdown of the last remnant of the suprarenal system, and thus the detoxifying influence of the suprarenals was entirely abolished. He reports this case to call attention to the fact that arsphenamine therapy is fraught with danger in patients with Addison's disease and states that, although the German medical literature has given little attention to this problem, it has been repeatedly discussed in other literatures and that it has been pointed out that the administration of epinephrine is helpful in preventing such undesirable complications.

Vitamins and Hormones—Kühnau and Stepp discuss the relations between vitamins and hormones. Recently it has been shown that the animal cell participates in the preparation of vitamins and that the exogenic origin, formerly assumed as self evident, can no longer be considered a characteristic quality of the vitamins. There are interrelations and transitional states between vitamins and hormones. The knowledge about the interrelations between vitamins and hormones has been advanced by chemical studies and by biologic experiments. It has been found that the relation between fat soluble vitamins and the hormones of the gonads is based on their chemical relationship. The authors illustrate this with structural formulas. They cite biologic observations on the correlations between vitamins A and B, the thyroid and iodine

metabolism Vitamin B influences thyroidal action, and under normal conditions there seems to be a relation between the suprarenal cortex, the thyroid and vitamin B The authors discuss the influence of vitamins A and E on the sexual functions, the relations between the anterior lobe of the hypophysis and vitamin E, and the synergism of vitamin D and the hormone of the parathyroids

Fecal Concretions in Vermiform Appendix—Aschoff discusses the pathogenesis of the fecal concretion of the vermiform appendix He evaluates the significance of fine hairs as determining centers of fecal concretion and the part played by fecal impaction, and he points out that the etiologic significance of the fine hairs is not fully understood as yet and that it is not even known whether the fecal concretion develops in the appendix or is forced from the cecum into the appendix In this connection he discusses the function of the vermiform appendix and the physiologic stasis of feces and shows that the movements of the appendix differ from those of the other portions of the intestine He describes his observations on the oxydase reaction of the fecal matters and of the layers of mucus Since the concretions of the vermiform appendix consist largely of mucous layers, he thinks that inflammatory conditions in the appendix are a factor in the development of the mucous layers, because inflammation results in excessive secretion of mucus As the bacteria found in the mucous layers of the appendix are those that occur in the appendix, the author concludes that the fecal concretion causes an attack of appendicitis not as a result of its mechanical action but rather because its mucous covering favors the growth of microorganisms that, under certain conditions, reach such a degree of virulence as to provoke an attack

Diagnosis and Therapy of Gonorrhea in Men A Wiedmann—p 78
Therapy of Genital Hemorrhages During Puberal Period O Reichelt—p 81

Hyperglycemia and Glycosuria in Coronary Thrombosis—Scherf calls attention to the frequent occurrence of a temporary hyperglycemia and glycosuria following coronary thrombosis He found these two signs missing in only two of eight cases In discussing the significance of hyperglycemia and glycosuria (rarely also acetoneuria), he points out that they cannot be the result of the intense pain only, nor merely the accompanying manifestations of the shock, because they were observed in patients without shock and with still high blood pressure Glycosuria of short duration was even observed in a patient in whom the coronary thrombosis was painless The author thinks that, in addition to other factors, the changes in the regulation of blood pressure are of great significance, since glycosuria was present at a time when the blood pressure was still high Moreover, the resorption of the decomposition products of protein, the high carbon dioxide content of the blood, and pharmaceuticals, such as morphine, caffeine and epinephrine may be causal factors in the development of hyperglycemia

Climatotherapy of Children—Moll recommends sea climate for children with chronic catarrhs of the upper air passages and for those with chronic cough, coryza, pharyngitis, tonsillitis or eczema, for children in whom tuberculous infection has taken place and in whom it becomes manifest as an enlargement of the bronchial glands and for those with extrapulmonary tuberculous infection either of the skin or of the joints Sea climate has curative value in children convalescing from severe bronchitis pneumonia or pleurisy Neuropathic manifestations, with the exception of the severe forms, constitutionally weak children and those with late rickets are also benefited by sea climate However sojourn at the seashore is not advisable in active tuberculosis, renal disease, articular rheumatism otitis media and cardiac defects The author recommends mountain climate particularly for anemic children,

because the reduced oxygen tension of the mountain air stimulates blood formation Sojourn in the mountains is beneficial in beginning pulmonary tuberculosis, but only in mild cases It is essential that the exposure to sunshine be carefully regulated Mountain climate is also advisable for children with tuberculosis of the glands or bones Constitutional weakness and retarded development is favorably influenced by mountain climate as well as by sea climate Children who, as the result of endocrine disorders, are obese or are inclined to laziness, and children with puberal disturbances should be sent to the mountains Those with bronchial asthma require a prolonged stay in the mountains The warm high mountain climate is beneficial in mild cases of chronic articular rheumatism and in nephritis For children who do not tolerate the strong climatic change, a mild inland climate is advisable in preference to the stimulating mountain or seashore climate A warm inland climate may be considered for those children who have renal disorders, articular rheumatism and neuropathic and psychopathic disturbances, such as chorea, epilepsy and paralysis

Method of Forming Intestinal Fistula with View to Its Later Spontaneous Closure. D Sarafoff—p 198
Early Diagnosis of Carcinoma W Mayer—p 212

Cicatricial Stenoses of Esophagus—The question of permeability of a cicatricial esophageal stenosis in the past was determined by attempts to pass sounds or filiform bougies The roentgenologic method of investigation introduced at a later date was easier for the patient and at the same time rendered more reliable information regarding the degree of stenosis The chemical test, introduced by Lotheissen, gave even more exact information In this test, the patient is made to swallow a small amount of a 2 to 5 per cent solution of ferrous lactate To the gastric contents, obtained five minutes later through the gastrostomy opening, are added a few drops of a solution of potassium ferrocyanide In the presence of the smallest amount of ferrous lactate, a bluish discoloration takes place The author points out that a stricture may be impassable from above but passable from below In cases in which the chemical test was negative there was no alternative to the difficult many-stage plastic procedures on the esophagus by the anterior thoracic route With the introduction of the electrolytic sound, the indications for operative intervention were still further reduced The method conceived by E Boeckel was further developed by Lotheissen of Vienna It consists in the introduction through an esophagoscope of a copper wire ending with a screw, to which a metallic olive can be attached The sound is connected with the negative pole of an uninterrupted current, while the positive pole is applied to the patient's back A current of from 2 to 5 milliampères is employed and the treatment is continued for not more than five minutes The aim of the treatment is to induce hyperemia and to render the scar moist, thus making it more yielding to the sound After some time the sound passes the obstruction without the use of any force This occurs in some of the cases in the course of the first treatment, in others at the second or third treatment To avoid burning of tissues, the treatments are given from five to seven days apart As soon as the sound passes into the stomach, the end of it is brought out through the gastrostomy opening and a continuous sounding is made possible Demel reports two cases of a supposedly complete stenosis rendered permeable by this method He believes that truly impassable strictures are rare The employment of the electrolytic sound, in his opinion, will still further reduce the number of operative cases

*Symptoms and Treatment of Opisthorchosis. V I Kondratiev—p 140

Opisthorchosis—On the basis of his clinical observations on the Siberian liver fluke disease in man, Kondratiev makes the following deductions 1 Opisthorchis felinus (liver fluke)

produces definite anatomic and functional changes in the liver, the gallbladder and the biliary tracts, at the same time influencing the general condition and the nervous system of the host 2 A moderate eosinophilia is frequently observed This, however, may be absent in lowered states of health 3 Injections of emetine hydrochloride improve but do not cure the condition Emetine has a cumulative effect which cannot be foretold because of idiosyncrasy to the drug 4 Owing to the wide spread of liver fluke infestation in western Siberia, patients with symptoms referable to the liver and the gallbladder should be examined with particular regard to the presence of ova in the feces and in the duodenal contents

- *Tuberculous Empyema C A Hedblom—p 311
- A Study of the Arteries in Two Cases of Raynaud's Disease J Ipsen—p 482

Ileus in Liver Cirrhosis—In a discussion of the diagnosis of ileus, Anschütz emphasizes the importance of the metallic clinking intestinal sounds and of the roentgenologic demonstration of fluid levels in the abdomen The latter may be considered pathognomonic In addition to the well known forms of ileus, he describes a rare form heretofore not mentioned in medical or surgical texts, namely, that of ileus in liver cirrhosis His experience with this form embraces a group of six cases verified at necropsy and of two cases not so verified The author points out that the onset was acute in only one case, that the pain symptom was not prominent and that the presence of liver cirrhosis was recognized before the operation in but one instance Ascites and intestinal distention obscure the presence of an enlarged liver or spleen All the patients operated on died The nature of ileus is probably of reflex origin The differential diagnosis is difficult unless one bears in mind the possibility of a liver cirrhosis Operation is contraindicated Opinion and atropine are valuable in the treatment

Pancreatic Tumor with Hypoglycemic Status Epilepticus—Bast and his associates report a case in which a man having epileptiform seizures for two years was found to be suffering from pronounced hypoglycemia The hyperinsulinism was not produced as the immediate result of overstimulation of the pancreas by food Relief from all symptoms was afforded by frequent feedings At operation a tumor was removed from the tail of the pancreas Detailed study of this mass suggests that it may have to be considered a carcinoma Various types of cells are shown in photomicrographs The abnormal cells include some which have a partial resemblance to beta-cells The atypical cells are to be correlated with the atypical occurrence of symptoms The diffuse distribution of abnormal cells may be associated with the persistence of symptoms for two weeks after removal of the tumor Relief remained satisfactory eight weeks after operation

Tuberculous Empyema—According to Hedblom, tuberculous empyema may be primary or secondary to a pulmonary lesion It is proved to be tuberculous by the microscopic demonstration of tuberculosis bacilli in the exudate, by culture, by animal inoculation and by the demonstration of tubercles in the pleura by thoracoscopy (Jacobæus) or by biopsy It may be secondarily infected by pyogenic bacteria A complicating bronchial fistula usually results in secondary pyogenic infection Thoracotomy drainage always results in secondary infection The aim of treatment of a primary tuberculous empyema, not secondarily infected with pyogenic organisms, is obliteration of the cavity by reexpansion of the lung This may be accomplished in whole or in part by substituting a negative tension pneumothorax for the pyothorax If a residual cavity persists, it may be obliterated by an extrapleural thoracoplasty

In case of a tuberculous empyema sterile to pyogenic culture, complicating an active pulmonary tuberculosis on the same side, the aim is to obliterate the cavity by an extrapleural thoracoplasty in several stages following aspiration of the pus A tuberculous empyema secondarily infected with virulent pyogenic organisms requires immediate adequate drainage to combat the pyogenic infection Closed drainage (Bülau) with frequent irrigation of the cavity is tolerated by the patient far better than rib resection and open drainage, but in case there is a large bronchial fistula open drainage may be necessary After the secondary infection is controlled, a thoracoplasty is usually necessary to obliterate the cavity in the primary type, and in the secondary type the pulmonary tuberculosis and empyema furnish a double indication for it A secondary resection of the parietal pleura usually is necessary to the obliteration of an infected residual cavity In a series of 143 cases of tuberculous empyema, sixty-one patients were treated by aspiration, irrigation and drainage, and twenty-two died (36 per cent) Eighty-two were subjected to radical surgical treatment, twenty-three of these had no secondary infection and the cavity was obliterated in eighteen (74.7 per cent), there was no mortality Fifty-nine had secondary infection, the cavity was obliterated in thirty-eight (64.4 per cent), but a sinus persisted in nineteen, twelve died (20 per cent) The mortality in tuberculous empyema is due in a large measure to active tuberculosis and to a virulent infection, or to their combined effect Cavities should be obliterated early to prevent infection When present, the first objective should be to combat it

- *III Continued Investigations on Mineral Metabolism During Pregnancy and Lactation Osteoporosis—Rickets K U Toverud and G Toverud—p 18
- *Diagnosis and Treatment in Diseases of Iliosacral Joint J Hald—p 32
- Apoplectic Disorders of Sensitivity K Zeiner Henriksen—p 49
- Lead Poisoning in Shipyard O Lorange—p 65

Cultivation of Tubercle Bacilli—Danbolt cultivated tubercle bacilli directly from tuberculous tissue by Lowenstein's sulphuric acid method in thirty-four out of thirty-six cases (thirty of lupus vulgaris and six of scrofuloderma), or 94.5 per cent Attempts to cultivate tubercle bacilli from excised tissue in sixteen patients with skin diseases considered related to tuberculosis were unsuccessful Of the nineteen cases of lupus vulgaris in which simultaneous inoculation in guinea-pigs was done, sixteen gave positive results both on direct cultivation and on inoculation He says that the direct cultivation of tubercle bacilli according to Lowenstein can give quicker results, is more easily carried out in the clinic, and is less expensive than inoculation in guinea-pigs, and can partly replace, partly supplement the latter, as there are strains of tubercle bacilli that are pathogenic to men but not to guinea-pigs

Mineral Metabolism During Pregnancy and Lactation—The Toveruds found that a cod liver oil dosage, though fully effective and present in sufficient quantity during fetal life, lactation and further growth, cannot protect the bone system from undergoing an extensive osteopathic process when the quantity of minerals in the diet is low

Diseases of Iliosacral Joint—Hald says that after the age of 30 the iliosacral joint shows a rising percentage of pathologic changes and tendency to spontaneous ankylosis The most common cause of iliosacral diseases is either trauma or chronic infection The most constant observations are tenderness along the inferior sacro-iliac ligament and the tuberosity of the ischia and pain on compression of the pelvis Bending while standing is greatly limited Radiating ischial pain always suggests a possible disease of the iliosacral joint Positive roentgen results are seen in only 2 or 3 per cent of the cases In acute iliosacral diseases, treatment is conservative In chronic cases a successful arthrodesis may be the best treatment In early cases of tuberculous inflammation of the joint, operative treatment is possibly better than the conservative

BASIC CONSIDERATIONS IN MINORITY REPORT OF COMMITTEE ON THE COSTS OF MEDICAL CARE

ALPHONSE M SCHWITALLA, S.J., PH.D.
ST LOUIS

Timeliness or untimeliness cannot, to my mind, be considered valid argument for the acceptability or the nonacceptability of a theory or of a social program. The advocates of the majority report of the Committee on the Costs of Medical Care those in professional ranks as well as those in the lay ranks, are fond of stressing the thought that the recommendations of the majority are a direct response to the needs of today and that they parallel to a remarkable extent today's social trends and tendencies. Attributing to this laudatory statement its full value, it is clear that the acceptability of the recommendations of the majority rests entirely, as far as this argument is concerned on the acceptability or the nonacceptability of today's trends and tendencies. If the latter are desirable or acceptable, then in all likelihood their outgrowth may participate in the acceptability or nonacceptability of the parent stem. Any argument based on the timeliness of the recommendations of the committee can lead us far afield into discussions of the spirit and the social theories of the age in which we are living.

We cannot help but question the meaning for the present and the significance for the future, of those subtle directional forces which today sway our social thinking, our governmental policies and the seethings of the popular mind. Each man who gives thought to these phenomena will probably form his own independent conclusions regarding the adequacy of any formulation. In this direction therefore, there lies little hope of national unanimity. Whatever one may conclude however, it must be granted that in one sense at least the recommendations of the committee mirror the day in which we live. They are essentially pragmatic, they are a direct answer to yearnings of the masses, a responding call to popular clamor. They are based on concepts of society, the functions of government, the state's responsibility for the individual, the governmental control of social factors and agencies, the federalization of the professional activities—on all of these and on many similar expressions of the popular mind of today.

CRITICISMS OF THE MAJORITY REPORT

For this reason I wish to emphasize the fact that the minority did not condemn wholesale and in toto the recommendations of the majority. The minor-

ity expressly states that, on many points discussed in the majority report, the nine members who signed the minority report are in complete agreement with the larger group. The minority says:

We are in full and hearty accord with the Majority in its recommendations for "The Strengthening of Public Health Services" and "Basic Educational Improvements," and we agree to some extent with the pronouncements of the Committee in respect to coordination of medical services.

The minority says, furthermore:

Some of the recommendations for coordination of medical services and for basic improvements in medical education are immediately practicable

and it considers itself "in sympathy with the recommendations of the majority which deal with the better training of specialists and their proper control."

It seems important to make it clear that the minority has not severed its interests from the report as a whole but has filed before the forum of public opinion its objections to a number of the attitudes and conclusions developed by the committee. I, for one, cannot accept the criticism made in several quarters that the money spent on the investigation now just concluded has been wasted, on the ground that even within the committee the studies failed to develop unanimity. It is argued by certain people from this fact that the report probably will fail more egregiously still when the people as a whole have taken hold of the committee's corporate thinking. My prognosis is rather that the fact that the minority report has been developed has really lent force and strength to the pronouncements of the majority. It must be obvious, after all, that to secure unanimity of opinion from as large a group as that represented by the majority is an achievement distinct in itself and worthy of the highest commendation. Besides, the fact that there has been a minority report might not only have been anticipated but even eagerly expected, since through this twofold report the recommendations of the majority have been much clarified and will thus serve better as a basis for a practical program. I see the values of the majority report for the following reasons:

- 1 It has made possible the accumulation of data second to those developed by no other investigation in any country known to me, in their value for an appreciation of medicine in our present-day civilization and our social status.

- 2 It has stressed the importance of the public health point of view and public health activities not only for their financial value to the community but also as programs for the effective betterment of our population.

- 3 It has presented the case for educational requirements in the practice of medical professions on the basis of well considered and well balanced statistics.

For the same reasons, I cannot bring myself to accept some of the criticisms that have been urged against the recommendations of the majority. It has been repeatedly said that the various studies have represented *ex parte* pleading, the innuendo being that the accumulated statistics represent efforts to prove theories through statistics rather than efforts to discover theory out of a mass of statistics. This procedure as a statistical method could be considered fully justifiable even if it were true that the committee had so used its statistics. But it is probably not true, even though the weaknesses of some of the policies advocated have not received the same measure of study as the successful ventures in several of the fields of medical practice. Besides, it cannot be regarded as a settled policy that one must always in social research investigate with equal thoroughness the contrasting manifestations of social tendencies. The methodology of social research can fully justify the separate study of any social manifestation that is expressible in factual data.

Lastly, I cannot accept the criticism implied in the remark that the committee has failed to reach a conclusion which embodies a single remedy for the present-day evils of medical practice. It seems to me that this comment, far from being an adverse criticism, is in reality a commendation of the committee's work, all the more valuable by reason of its spontaneity and its character as allegedly adverse criticism. The variety of recommendations shows that the committee has been fully aware of local and regional differences of time, place, social condition, economic status and the many other factors which are variable from day to day and from place to place and which make it necessary for the legislator, the student of contemporary social history, and the economist to modify programs, to invent substitutions and to create responses to new demands.

I therefore cannot withhold my admiration for the work of the committee as a whole. My strictures, such as they are, pertain, therefore, largely to some of the implications of the recommendations made by the majority.

MEDICINE AS A SELF-DETERMINING PROFESSION

As I see it, the two reports differ radically in their attitude on the self-determination of medicine, the minority report stressing the rights of the medical profession to this self-determination, and the majority report greatly modifying, if not completely obliterating, the profession's right to this self-determination. If the recommendations of the majority report prevail, it seems to me that medicine will have to give up its traditional policy of aloofness, its sempriestly character, its reputation for unselfishly contributed services, and its boast that it has withstood even the most severe and brutal inroad of commercialization.

The attitude of the minority favors self-determination and self-adaptation of medicine, the attitude of the majority favors, as I see it, the coercion of medicine through social stresses and economic need.

My concern, therefore, is first and foremost for the preservation of those standards of medical practice which have made medicine what it is today, a profession which, with all its defects and shortcomings, its failures and deficiencies, is still the most outstanding, the most successful, the most altruistic of the professions dealing with the physical life and the social environment of man.

It seems strange that in this day, when we have learned to regret the apotheosis of big business, of its methods and its accomplishments, we should seek to open doors thus far closed to the methods of big business. We have ceased to worship at the shrine of commercialization and now when this has been proved unsuccessful on an individual as well as on a national level, we seem suddenly to be urged on by the desire of introducing these discarded methods into the practice of medicine. Is not the procedure somewhat out of date? Ten years ago, perhaps even five years ago, enthusiasm for such methods might have been justified when it was customary to laud our culture and civilization as the outgrowth of our credit system, our financial programs, our sales appeals and our effective marketing. It would not have seemed strange in the moment of ascendancy of all these procedures if some "great leader" had taken medicine by the hand and attempted to lead it to the pinnacle of the sales curve, to the high plateau of the commodity distribution curve. In those days, the mounting graphs in the world of finance and business appealed to us with convincing cogency, but today things surely are different. We have seen these curves tobogganing into the depths. It is anachronistic to ask medicine today to pursue policies which have failed to carry out their promises and which have served their bankruptcy notice on our people.

We have learned the bitter lesson that organization by itself does not spell the redemption of mankind. Organization cannot create values, although it may redistribute them and render them more effective. The value of organization arises from the intrinsic value of that which is organized. Inadequate medical care by a group of individual physicians does not become adequate medical care when that group organizes. A hospital by itself in the midst of its community that is rendering fair service cannot have that service elevated to a higher level of excellence merely by reason of superorganization. Merely to call a hospital a medical center or even to effect its reorganization as a medical center does not change the status of the institution in its potential effect on the community. An insurance plan which rests for its effective value as a public servant on market conditions is not elevated into a stable concern merely because its beneficiaries now receive the tangible and intangible services rendered by the science and art of medicine. It seems to me that herein lies one of my own difficulties with the majority report, that the method of administration in rendering medical service has been overstressed to the neglect of the more basic need for a reform in the art and science of medicine itself. And in the same way it seems to me that the minority report, although it had to be hurriedly assembled, still comes closer to the medical needs of today by stressing the character of the service given to our people rather than the administration of that service.

I cannot accept the rejoinder that the committee was concerned rather with the economic costs than with the character of the service. The committee was aware of these implications and registered its awareness on the day when it voted to substitute the name "The Committee on the Costs of Medical Care" for the former name, "The Committee on the Cost of Medical Care."

Medicine itself as a self-determining profession must, if it is to fulfil its high character, develop those standards of service the need of which has become increasingly felt with the passing of time. Standards

imposed from without through the coercive force of extraneous agencies are probably no more effective in the domain of social betterment than external reform is in the domain of individual betterment. The best laws do not of themselves make nations better. The best rules are not a guaranty by themselves of an institution's excellence.

As a third consideration under this head, I should like to enter my protest against the fallacious argument that medicine must respond to the social trends of the day if it would remain alive and retain its force. Aside from the fact that those social trends are highly ambiguous, as pointed out before, the argument cannot stand of itself. It is true that medicine must adapt itself, but the first law of nature is not adaptation, it is self-preservation. It must not be assumed that that first and fundamental law can be violated only by a failure to adapt on the part of the organism. It can be violated just as disastrously by overadaptation. The paradox of adaptation lies precisely in this, that a measure of isolation spells continuance of life, exaggerated adaptation means death. The organism which adapts itself to environment with a measure of restraint and with a cautious degree of self-originated inertia is the organism which successfully meets the environmental stresses and persists in life. The organism, however, which merges with its environment, which is nonselective among the impinging forces, which reacts actively to every stimulus as if every stimulus were of necessity to be an effective stimulus, that organism is preparing its own doom. Even if the social trends of the present day were well defined and unidirectional, medicine could not afford to sacrifice its individual and aloof isolation as a distinctive social force without giving up the very qualities and prerogatives that have made it what it is. It may yield to economic pressures for a time, but in the end such yielding may force concessions which spell deterioration rather than development. We need not labor the point too much. It is clear, it seems to me, that the minority's stand on the uniqueness of medical service is a thought replete with the deepest significance for the future of medical care. We must recognize what the present day demands of medicine, but the medical man must know better than those who are not medical men whether those needs should be gratified by his own yielding to ephemeral phenomena.

PERSONAL RELATIONSHIP OF PATIENT AND PHYSICIAN

A second contrast in point of view as evidenced by the two reports refers to the concept of the medical profession itself. I myself cannot quite adjust the convictions concerning the practice of medicine engendered in my own mind through more than twenty years of intimate contact with the medical profession, with the points of view expressed in the majority report. In this connection one can be easily misled. It is strange that both the majority and minority reports seem to stress the question of personal relationship between physician and patient but when one examines the comments made on this personal relationship one cannot but note rather astonishing contrasts. It has been pointed out frequently that the mere wording of a principle is no guaranty of its specific application. Thus, for example both the insurance agent and the socially minded physician may use identically the same words in making a plea for the reduction of medical costs in favor of our middle classes. In the case of one the words may spring from a mind deeply filled with ideals

of public service, in the case of the other, they may issue from a mind immersed in self-interest.

With this in mind, we may now turn to an examination of the pronouncements on the personal relationship of patient and physician. The majority report says on this point (p. 30) "The preservation of a personal relationship between patient and physician is an essential element in safeguarding the quality of medical practice. This relation as the Committee defines it includes 'not only the privileged confidential communications of patient to physician which are recognized as inviolate by law, but also the relation involved in the communication of his medical history to any physician chosen by the patient and the continuing mutual responsibility between the patient and the physician.'" The majority report farther on says (p. 41) "There is nothing in any way mysterious in the relation between the physician and his patient. On the therapeutic side it is capable of completely objective analysis. As to those phases which are not strictly medical, it is of a piece with all satisfactory human relations involving as they do mutual patience, sympathy, understanding and confidence." The minority report, on the other hand, has something quite different to say on this point. It, too, stresses the importance of maintaining the personal relationship (p. 169) "By personal relationship is meant that bond of sympathy and interest in the patient's welfare on the part of the physician, confidence in the ability and integrity and discretion of the physician on the part of the patient, and mutual regard on the part of each for the other which cause the patient to disclose for the purpose of diagnosis and treatment the most private and confidential information concerning himself and his surroundings when necessary for proper diagnosis and treatment. The character and personality of the physician is a major factor in its development and in process of time and continued contact as patient and physician, a friendship and intimacy develop that assumes priestly characteristics on the part of the physician, the characteristics of the confidant and adviser in the most intimate personal and family relationships. It is an individual relationship, the product of character and personality, and cannot be transferred to a group or fostered by group practice."

It might be highly interesting to analyze in minute detail the expressed and implied points of view in these two quotations. Suffice it to say that to my mind the quotation from the majority report leaves much to be desired and much more to be questioned concerning the ethical and ideal requirements in the practice of medicine. I cannot, first of all, subscribe to the implication that the only or the chief element in the personal relationship between patient and physician is the safeguarding of confidential communications. The character of the implied contract in that relationship is much more comprehensive and overflows in its effects into ever so many basically human interests. Secondly, I am inclined to think that the committee's definition of this personal relationship was manufactured "ad hoc," since it is so carefully worded to make it possible to base on this definition many of the suggestions that flow from this basic principle. In the majority report itself this is clearly recognized, since the business relationship between the patient and the physician is not considered a necessary part of the personal relationship as defined above. As a third point, I might mention that I cannot accept the statement that "on the therapeutic side it [the personal relationship] is capable of completely

objective analysis" On the therapeutic side, to my mind, as well as in those phases which are not strictly medical, the relationship of patient to physician implies psychologic, moral, spiritual interrelationships which are not susceptible as yet, at least of that "completely objective analysis" which we bring to bear through the scientific method on, for example, our vital statistics or our scientific or clinical investigation The minority's pronouncement on this point seemed to me to probe more deeply below the surface and to reach more effectively into the very heart of the problem The minority's formulation implies more than diagnosis and treatment It recognizes the subtleties and the refinements of the relationship between patient and physician which from time immemorial have been upheld as the greatest claim of medicine to its position of pre-eminence among the merely natural professions

The corollaries drawn from this fundamental statement of the basic question are obviously forestalled in the two formulations The majority report draws from its formulations of the personal relationship the conclusion that group practice in one of its many forms is a desirable and perhaps a necessary development of present-day medicine The minority report, on the other hand uses its formulation of the basic relationship as a plea for the restoration of the general practitioner to a central place in medical practice The majority report pleads explicitly or implicitly for mass medicine, the minority report for a higher degree of individualization in medical practice The majority report calls attention to the feasibility and desirability of group purchase of medical service, while the minority report issues a word of warning against some of the most undesirable features of group purchase

I myself have little difficulty in making a choice between these two points of view The matter can hardly be treated here at great length, but it seems to me that, even from the statistics so ably assembled and presented by the experts working with the committee the conclusion unquestionably obtrudes itself that some way must be found by which the enormous machinery can be reduced which in certain quarters has been devised for the physical and medical care of groups of individuals, if the financial cost of medical care is to be reduced effectively Methods of mass production may well be considered effective in industry It does not follow that mass production is effective in all lines of human endeavor Certain phases of medical practice may be susceptible of "completely objective analysis," but my own experience as a patient in dealing with physicians makes me very skeptical concerning that analysis when I try to formulate the reasons why different physicians have given me different measures of satisfaction, not only in their human relationships toward me but also in their strictly professional activities I cannot be deeply impressed with endless tabulations of medical diagnostic and therapeutic activities The long processions of statistical data on the number of home visits, the number of telephone calls, the number of treatments as measures of professional adequacy, even vital statistics taken by themselves, are little more than the skeletons from which may be reconstructed, if one is shrewd enough, the vast organism of medical practice Of course, these things must be in our complex life They are measures of activity, necessary and desirable measures, without which much of the machinery of our everyday life would have to be discarded to the loss of the conveniences and facilities developed on our cultural level, but even when all this

is said, there still remains the fact questioningly staring us in the face that such statistics belong rather to the method of medicine than to medicine itself They cannot be regarded as substitutes for that more subtle and, to my mind, objectively unanalyzable contact between the physician and his patient

GROUP PURCHASE OF MEDICAL SERVICE

Lastly, I should like to comment, at least briefly, on the views of the majority and minority reports concerning the group purchase of medicine The public at large has probably regarded this phase of the committee's report as the central thought, of most interest to itself The majority report encourages experimentation with various plans of group purchase The minority report discourages such extensive experimentation and wishes rather to lay emphasis on the source from which emanates responsibility for the service purchased as well as for the purchasing power The minority recommends that "the corporate practice financed through intermediary agencies be vigorously and persistently opposed as being economically wasteful, inimical to a continued and sustained high quality of medical care or unfair exploitation of the medical profession" This is the minority's pronouncement on group practice Concerning group purchase of medical service, the minority recommends that "careful trial be given to methods which can rightly be fitted into our present institutions and agencies without interfering with the fundamentals of medical practice" The stress in the mind of the minority is on the safe-guarding of the "fundamentals of medical practice" rather than on the extension and development of financial schemes

Of course this pronouncement is an indicator of the minority's conservatism To be dubbed a conservative is an insult in the minds of not a few people I cannot so view it Organic growth is a conservative process just as is the process of self-differentiation In an epigenetic process, each succeeding step is told by the preceding step Medicine would do well to heed the lessons of ontogenesis Of course, the majority report has forestalled some measure of criticism under this head by stressing the thought that it is planning the development of medical practice for the next twenty-five or fifty years But to plan the integration of medicine into an unknown and precipitately evolving society without knowing, as we all confess we cannot know, the directional trends of the future and that at a time when we cannot even see the significance of present tendencies, is perhaps the most self-condemnatory statement which the majority could have made in comment on the committee's activities There may be certain forms of society into which group purchase of medical service could logically and consistently be integrated Ours probably is not such a form as yet It must not be forgotten that while there are enthusiastic advocates who see unquestioned success in the trial of those methods by other nations, there are still not wanting other critics who have pronounced group purchase of medical service on a national and also on a more restricted level not only as a medical but also as a social failure The minority regards some of the plans for group purchase as the frankest possible schemes for the commercialization of medicine What is implied in such a statement can hardly be amplified in this paper, suffice it to say that a commitment to policies which harbor the merest hint of such a danger may lead progressively to forms of legal regulations which will tie

a millstone round the neck of medical practice and submerge it under waves of selfish aggrandizement

CONSTRUCTIVE RECOMMENDATIONS OF THE MINORITY REPORT

The minority has not refrained from making constructive recommendations which, it is my personal belief, should be viewed with no less respect than the plans submitted by the majority. Essentially, the minority is concerned with retaining the medical profession's preeminence in any plans that may be formulated for the furtherance and greater effectiveness of medical practice, whereas the majority's proposals are concerned, it seems to me, rather with economic dominance in medical practice. To be sure, every summation of this kind may be unjustifiably general, but perhaps this formulation is as fair as any. The minority recognizes the necessity of readjustments of organized medicine and of the medical practitioner. This need is too obvious to require elaborate discussion. The point, however, lies in this: Shall that reform, if that word must be used, come from medicine itself or shall it come from a nonmedical source?

I should like to call attention to two aspects of this matter. First of all, the minority complains and, I believe, rightly that a thread of criticism of the medical profession binds together the various recommendations of the majority report, the implication being that medicine has been at a standstill. How unjust such an implication may be let those tell who have labored in laboratory and clinic and school and office during the last few decades. Of all the sciences, with the possible exception of physics, medicine has progressed with constantly accelerated speed. It has broadened and deepened and heightened its activities to a degree which all but paralyzes the mind that tries to follow and it has given us an insight into vital processes comparable in their significance to no other biologic discoveries of the past. And if it should be rejoined that we all recognize the scientific progress of medicine but that we complain of the lag in the application of the scientific discoveries, I can only answer that unfortunately such are the limitations of the human mind not only in medicine but also in all forms of human endeavor in which the observations of the research worker must be translated into action programs of the practitioner. We can, however, accelerate those applications if we enlist more and more the enthusiasm the services, the drive-to-do of those most concerned with scientific progress. In the field of medicine, whose interest can be more effectively aroused than that of the practitioner? We have an elaborate organization of medicine, not too elaborate, but elaborate enough. The hierarchy of local, state and national medical societies is second in the compactness of its organization to the organizations effected by scarcely any of the other professions. These groups can certainly be aroused to an increasing sense of their responsibility to the public.

At any rate, the evidence has not been presented, to my satisfaction at least, that we can afford to ignore organized medicine in any program looking toward the more effective application of medical science to the public. I am speaking not only of the American Medical Association but of those many other societies in special fields whose primary function, it is true, may be the promotion of scientific thought but which fully realize that scientific development has a profoundly important significance for human betterment and whose members are seriously concerned not only with abstract

truth but with the applications of that truth to human society. It is not my place here to review the minority's strong pronouncements on this matter or to restate the programs which it suggested for the development of plans for medical care by state or county medical societies. The important principle is that through the minority's program the direction of future evolution in medical practice is kept within the hands of the profession itself. The responsibility for that evolution and for the mechanism by which that evolution is effected remains vested in those to whom it belongs.

As a second thought, let me point out that I have no confidence in the growth of a profession by external pressure. Self-differentiation is the prerogative of the living organism. Growth is a spontaneous vital process not amenable to coercive or artificially restrictive measures. The profession of medicine is such an organism, it must grow and divide itself in response to its organic needs. External pressure may stimulate or retard, but such acceleration or retardation pertains only to the velocity of growth and differentiation but is not growth or differentiation itself. I am here referring not only to the processes in the development of general practice but also to the development of specialization. It would seem to be implied in several sections of the majority report that specialization can be brought about by arbitrary ways, by designating this or that physician to do this or that piece of work, by the ipse dixit of an authority controlling a group, or by the self-claims of this or that individual physician. Such forces do not make specialists. As medicine progresses, the specialty itself emerges and with that emergence is usually found the specialist who will devote his attention more and more to the new need, but both the need and the situation of the need must come from medicine itself. If this principle is accepted and acted on, the differences between general practice and specialization will be rapidly adjusted.

SERVICE DONE BY THE TWO REPORTS

The majority report, to my mind, has done its greatest service to medicine by arousing the interest of the medical man in the economic and social problems implied in medical practice. The minority report, to my mind, has done its greatest service to medicine by restating and reemphasizing those basic principles of medical practice which must be the foundation of all development in medicine, not only of scientific development but also of social and economic progress in the practice of medicine.

1402 South Grand Boulevard

Thrombocytopenic Purpura—Purpura hemorrhagica was first described by Werlhof, in 1775. Knowledge concerning the nature of the disease developed gradually, until even today there is no complete agreement as to the etiological factors concerned nor as to the mechanism by which these factors act. Denys, in 1887, first observed that the blood platelets were missing in a case of purpura. Nine years later (1896), Hayem showed that in purpura there was a failure of clot retractility. Duke, in 1910, demonstrated that a thrombocytopenia and fibrinogen lack have very definite effects on bleeding time. He pointed out that the reduction of platelets in purpura hemorrhagica is associated with an increased bleeding time, but not with any marked variation in the coagulation time. Hess showed conclusively that there was a marked weakening of the capillary vessels in purpura hemorrhagica as evidenced by the petechial and even large subcutaneous hemorrhages which developed distal to a tourniquet applied to the upper arm tight enough to obstruct the venous flow.—Eliason, E. L., and Ferguson, L. K. Splenectomy in Purpura Hemorrhagica, *Ann Surg* 96 801 (Nov.) 1932.

INVESTIGATIONS AND CONCLUSIONS OF THE COMMITTEE ON THE COSTS OF MEDICAL CARE

LEWELLYS F BARKER, M D
BALTIMORE

The Committee on the Costs of Medical Care after five years of activity, officially discontinued its work at the end of 1932. This committee was composed of some fifty members, among whom were representatives of the fields of private practice, public health, medical institutions and special interests, the social sciences and the general public. With the aid of a director of studies, an administrative staff and a research staff, generously supported financially by grants from several large foundations, extensive fact-finding investigations were undertaken and completed, the results of which were published in some twenty-six monographs. The implications of the facts revealed by the various studies were carefully considered, a tentative draft of recommendations was formulated and submitted to advisers and members for criticism, and on Oct 31, 1932, a final report entitled "Medical Care for the American People" was completed. This last document contains a majority report, two minority reports, and personal dissenting statements by two of the members.

All agreed that adequate scientific medical service and facilities should be accessible to all the people, no matter what their incomes are, that services for the prevention of disease and for the maintenance of positive health are necessary as well as curative services, that those who furnish the services should be properly remunerated, and that in the field of professional education there is need for extensions and for changes of emphasis to correspond to changing social and economic conditions and to the better recognition of preventive and administrative needs.

The majority report recommended as an ultimate goal (1) that medical service, both preventive and therapeutic, should be furnished largely by organized groups of physicians, dentists, nurses, pharmacists and others, organized preferably around a hospital, the service to include home, office and hospital care, with the maintenance of high standards and the development or preservation of a personal relation between physician and patient, (2) that all basic public health services be made available to the entire population according to the needs, (3) that the costs of medical care be placed on a group payment basis, through the use of insurance, of taxation or of both, though service on an individual fee basis for those who prefer it need not be precluded, (4) that the study, evaluation and coordination of medical service be considered important functions for every state and local community and that agencies for the exercise of these functions be formed, and (5) that certain much needed improvements in undergraduate and postgraduate medical instruction be made, that the social aspects of medical practice be given greater attention, and that the practice of the specialties be better controlled.

The principal minority report recommended (1) that government competition in the practice of medicine be discontinued and that government activities be definitely restricted to certain special fields enumerated, (2) that government care of the indigent be expanded so as ultimately to relieve the medical profession of the

burden, (3) that the recommendation of the majority with regard to the functions of each state and local community in the study, evaluation and coordination of medical service be approved, (4) that united attempts be made to restore the general practitioner to the central place in medical practice, (5) that the corporate practice of medicine, financed through intermediary agencies, be vigorously and persistently opposed, (6) that methods that can rightly be fitted into our present institutions and agencies without interfering with the fundamentals of medical practice be given careful trial, and (7) that state or county medical societies develop plans for medical care.

It is obvious that the chief differences of opinion in the committee are referable to (1) the question as to whether medical practice shall be kept mainly in the hands of single practitioners or shall be the function of groups, organized about a hospital in a so-called medical center, and (2) the question of group payment for medical service by means of insurance, of taxation, or of both.

In the discussion of group service, those favoring the majority report believe that, with proper leadership, medical facilities can be so efficiently organized as to achieve economies in the production of medical care of all kinds needed, not only without sacrifice of the quality of service but with improvement of its quality and increase of its volume, and that the incomes of the medical practitioners supplying the service can be increased or stabilized above the level of the average net income of private practitioners, whereas those disagreeing with the majority report express the fear that the freedom of the participating practitioners would be restricted, that the doctors would inevitably come under lay control, and that the important personal relations of doctors to patients would be lessened or destroyed.

In recommending group purchase for certain income groups by voluntary insurance, by taxation or by both, those favoring the majority report believe that the costs of good medical service could be so distributed that they would be no hardship to any one and that more money could be made available for the cure and prevention of illness and for the maintenance of positive health than is spent for these purposes under the present system of private individual practice. Those opposing the recommendation of group purchase fear the dangers of mass production, the creation of medical hierarchies, obstruction to free competition, an inferior quality of service, a deprivation of the rights of patients to choose their own doctors, inadequate compensation of practitioners, and diminished attractiveness of medical work for men of greater ability who, they think, would be driven into other fields. Voluntary insurance plans, they assert, are only preliminary steps toward compulsory insurance, or toward the development of state medicine, and they point to the bad patterns of group purchase that were established, at first, in Europe when attempts were made to distribute the costs of medical care there, such plans some maintain are promulgated by "meddlesome Matties," often with selfish designs, and are bound to lead to the formation of "medical guilds," to "medical socialism" or to "medical sovietism" with all the evils that they believe to be inherent in such systems. The principal minority report has received staunch support from the Lowell Commission on Medical Education, despite its recognition of the evils that result from excessive competition, overcrowding of the pro-

profession, specialization, prohibitive costs and poor distribution of modern facilities—evils that must be, it thinks, corrected by the coordinated effort of colleges, societies, hospitals and health services—this commission believes that there are fundamental advantages in the American form of practice that would be lost if group practice and group purchase were to be adopted.

Similar divergence of views has been apparent among members of the dental profession, though the nursing profession, hospital administrators, public health workers, and the executives of the great philanthropic foundations have, on the whole, tended to support the recommendations of the majority report.

That the organization of medical practice and the distribution of the costs of medical care must undergo some alterations because of the advances of medicine and the continually changing social and economic conditions would seem certain.

The advocates of the recommendations embodied in the majority report foresaw many of the objections that would be raised and laid stress on the importance, in applying any insurance principle, of complete separation of the costs of medical care from the cash benefits that go for loss of wages due to illness, they also stressed the desirability of avoiding any mechanization of medicine, of preserving the right of selection of attending physicians, of insuring the maintenance of the highest quality of medical service and facilities, of avoiding any interference with the desirable personal relationships of doctors and patients, of keeping the control of the professional aspects of the work entirely in the hands of medical men untrammelled by the dictation of laymen, of making steady evolutionary progress rather than revolutionary change, and of trying various methods of approach to the goals visualized by adapting any changes made to the special needs of each local community rather than by the adoption suddenly of any nation-wide or even state-wide method of group practice or group purchase.

Despite the bad patterns established at first in Europe, no country that has resorted to the principle of insurance has given it up and the patterns more recently followed in Denmark and Sweden are free of some of the evils of the older methods. Students of medical conditions in countries in which insurance plans are in vogue assert that the average care of the sick is better than it was before insurance was introduced and that the average income of the doctors providing the services is larger than before. It must be admitted, however, that the mortality rates have not decreased under insurance systems, that the average number of illnesses has increased, and that certain new syndromes—the ‘compensation-neuroses’—have often been in large part directly attributable to desire for benefits by the insured.

The medical men who were members of the Committee on the Costs of Medical Care have had a feeling of deep responsibility both to the profession to which they belong and to the public served by that profession. They were desirous to avoid any attitude that would be obstructive to needed reforms but they also sounded words of caution against any sudden and rash ventures into dangerous areas. They favored, therefore, the making of a variety of experiments, especially by local groups in the hope that observation of the results of different types of effort might in time lead to wider adoption of those that proved to be best.

A total unwillingness on the part of the medical profession to participate in trials of the proposed methods of organization and of payment might easily be misinterpreted by the public, and a warning against too negative an attitude would seem to be in place. One need only recall the fact that the violent opposition of medical men did not prevent the introduction of health insurance in Germany or in England, but it put the doctors in a false light, excited public hostility, gave rise to the idea that the physicians were selfish rather than public spirited, and led to the exclusion of medical influence and leadership from the making of the plans. Since it seems certain that certain types of voluntary or compulsory insurance will inevitably be given a trial in the United States, it would seem to be wise for medical men to attempt to direct them along the routes that appear to be least objectionable, keeping control of the medical policies so as to avoid as far as possible the establishment of bad patterns here and seeing to it that whatever experiments are tried shall be thoughtfully controlled and the results thereof critically evaluated. In this way the medical men of America would profit by the mistakes of their European confreres, would keep the good will of the public, would maintain the dignity and ideals of the profession, and, at the same time, would discover what place, if any, health insurance ought to occupy in American health programs. There is no doubt at all in my mind that my colleagues in the medical profession want the forms of practice and the methods of payment that will be most conducive to the welfare of the American people, and whatever is really best for the people will, in the long run, be best also for the physicians and surgeons who serve them. In determining what is best, the vast amount of fact-finding work done by the committee and its staff of investigators, its careful consideration of those facts, the recommendations made by both the majority group and the minority groups, and the widespread discussion of the report throughout the country ought to prove to be most helpful in reaching decisions regarding the best methods of providing adequate medical care for our people at costs well within their reach.

1035 North Calvert Street

Private Practitioners and Preventive Medicine—In America as in this country, it is being recognized more and more that the private medical practitioner, and especially the general practitioner, is one of the most powerful agents of preventive medicine, and that he may claim to rank at least equally in this field with his two great colleagues—the public health medical officer and the research worker. It is a mistake to try to gauge the relative importance of the work of each of these three still less is it necessary for any one of them to vaunt himself above the others. They should be regarded as a team, each of whom must avail himself as fully as possible of the services of the others in order that full public advantage may be secured. In this country, as perhaps everywhere, the discoveries of the research worker take far too long before they are actually put into common practice, the public health medical officer too commonly still regards the private practitioners of his area as engaged in a separate sphere of professional work, and those private practitioners continue to pursue their daily activities in preventive as well as curative medicine without realizing as they should, that they ought to be a continuous and integral part of the public health organization of the area. Private practitioners were the earliest agency in the prevention of disease. They have never ceased to be such agents. Yet it is only now that they are beginning consciously to recognize themselves—or that the public is beginning to recognize them—as one of the most effective and essential of such agencies.—*Editorial Brit M J* 2 413 (Aug 27) 1932

PREPAYMENT PLANS FOR HOSPITAL CARE

R. G. LELAND, MD

Director, Bureau of Medical Economics, American Medical Association
CHICAGO

Although it is claimed that the temples of Saturn represent the origin of hospitals, thousands of years passed after this alleged classical beginning before civilization had developed to an appreciation of and a demand for buildings set apart exclusively for the care of the sick, even in the largest urban centers. Hospitals of the early centuries of the Christian era were established for various purposes—the housing and relief of orphaned children, the aged, the poor, the infirm, the lame and the blind, and for lepers outside the towns. These were charitable, relief and service institutions and no doubt contributed much to the comfort of the unfortunates who applied for succor. It is not definitely known, in each instance, to what degree medical care and nursing constituted the functions of these early hospitals but it should be clear that the expansion of this phase of hospital service was directly dependent on the progress of general science and medicine.

The hospital in its modern sense was but slowly created. Certain of the early types of service seem to have persisted, and these are now found in institutions organized for special purposes such as children's hospitals, city and county hospitals for the poor, orthopedic hospitals, maternity hospitals, communicable disease hospitals, and hospitals devoted exclusively to the care of eye diseases. It seems safe to infer, therefore, that hospitals have followed the developments in medical knowledge and have been organized to provide service in both the general and the special fields of medical practice.

Since hospitals have furnished a service which, in certain instances, has contributed to the facility of medical practice and to the safety and comfort of the patient, the ideals, customs and ethical principles governing hospital practice have gradually been brought closely to parallel the principles of ethics of the medical profession. If the medical profession and hospitals are to serve the public on an equally high ethical and professional plane, the ideals and objectives of the two institutions must be identical.

There seems to have arisen some confusion relative to the capital investment of the medical profession as compared with the capital investment of hospitals. Although each physician must expend, for his preparation and physical equipment, a certain amount of cash which may be considered a portion of his capital investment, before he may practice medicine, the larger and ever increasing chief capital investment in medicine is represented by the constantly accumulating body of knowledge, a capital fund which is not the property of any individual or group of physicians and the benefits from which the profession has always freely made available to the public.

This may be compared with and contrasted to the constantly increasing value of hospital, clinic, laboratory and allied properties and equipment. This capital, with some few exceptions, is not held exclusively as an individual or group asset, in the majority of instances it constitutes, broadly speaking, a trust investment for the good of the community, in reality a social

possession. Even in the case of the privately owned institutions there is a definitely implied social interest.

The real medical capital, first mentioned, consisting of accumulated knowledge, is stored in the minds, ideals and traditions and in the publications of the medical profession and is shared freely with the public through universities, journals, discussions, the public press, radio and individual consultations. This capital cannot be monopolized for profit. It does not fit into the capital concept of industrial economics, yet it is the greatest asset of the profession. Without it all physical capital would be worthless.

The capital investment in hospitals is variously estimated at approximately \$3,000,000,000, most of which is organized or incorporated on a non-profit basis although about 10 per cent of this amount is to be found in hospitals organized for profit. This predominance of non-profit bearing hospital capital together with the support of these institutions by philanthropy and public good will is an evidence of the general acceptance of the social interest and possession concept of hospital properties and service. The entire investment in hospital properties, including those hospitals incorporated for profit, has been made for the benefit of the public. But the public can reap its benefits from these investments only to the extent that the physical capital of hospitals serves and assists the knowledge and experience possessed by the medical profession.

This fact of the dominance of the "professional knowledge capital" is of primary importance in the development of any program of furnishing medical service, including hospital care. Unless this immaterial "capital" maintains its dominance over the physical capital in any such program, the service itself suffers. The physical capital must remain the instrument wielded by the personal skill and knowledge.

During the past decade the physical capital of hospitals has been enormously increased. This expansion may have been in keeping with the general trend during the pre-economic depression period. It is difficult to show that this expansion always followed a well established need. It is also difficult to reconcile some of the cost of inordinately expensive construction and equipment with the requirements of good medical care. Nevertheless, the capital has been invested, interest becomes payable regularly, building bonds must be retired, and maintenance is necessary. Because of shrunken incomes there seems to be not only a diminished use of hospital service but, when hospital care is necessary, there is also increased difficulty in making collections. The incomes of philanthropists and supporting foundation funds have likewise contracted, thus somewhat affecting certain hospitals and institutions.

Sensing the financial pressure with which some hospitals are faced and utilizing the popular discussion about the costs of medical care, certain commercial interests have recently developed mass production schemes for hospital care seeking to create a larger market to provide more funds with which to meet the hospital overhead costs. It is significant that this attempt to capture the professions by the use of mass production methods in the marketing of medical and hospital care should appear just when industry and business are endeavoring to incorporate into their methods some of the characteristics of the professions. At present, efforts to "professionalize" business are being directed by trade associations, legislation and a host of semipublic bodies and interested individuals in an effort to restrain some of the excesses of business.

DESCRIPTIONS OF SCHEMES

With few exceptions, group hospitalization schemes are now being promoted by commercial organizations seeking contracts for from one to five years with hospitals for hospitalization membership campaigns. The contract with the hospital may or may not guarantee a definite number of members but it always states the commission on which the organization agrees to undertake the sales work. These commissions vary from 21 per cent to approximately 75 per cent of the amounts paid by the members. Members are usually secured in groups, although some organizations solicit individuals. The cost to members varies from \$6 to \$24 annually.

It is claimed by some of the promoters that free choice of both physician and hospital is granted the members, but obviously this is a misrepresentation whenever all physicians and all hospitals in a community are not included.

Certain contracts provide hospital care for workmen's compensation cases, although most promoters exclude these cases from contract benefits. In some cases, physicians' fees are collected and paid to the hospital apparently under the supposition that the hospital staff members are to make the home calls and give all other medical services without further remuneration. Some contracts provide, further, that no member may enter the hospital as a patient until examined by a member of the hospital staff.

Monthly contract payments by members are usually made by payroll deductions wherever members are secured in groups. Members are usually entitled to twenty-one days of hospital care during any twelve month period. Patients requiring more than the twenty-one days of hospital service are entitled to from 25 to 50 per cent reduction from the regular hospital rates. This reduction in rates is sometimes granted to the member's family.

There is a wide difference in the methods of handling funds. One scheme provides that the hospital giving the service may draw on the promoting organization for the full amount due, several plans provide for a flat per diem rate to be paid hospitals for the care of members, the balance remaining at the end of the year to be prorated among the participating hospitals, other schemes provide that the monthly membership premiums shall be paid directly to the hospitals, none of the schemes provide for an adequate safeguard of funds.

Although promoters have placed in their contracts certain limitations on service to which members are entitled, they have likewise included in several instances, as a part of the hospital care, a number of distinctly medical services which must be given by physicians without pay.

The experience in the field of group hospitalization is too limited to provide reliable data concerning the quality of service rendered.

CRITICISM

The principal merits of such plans are the following:

Limitation of these schemes to hospital care with restrictions as to length and character of services furnished and as to diseases covered makes possible more accurate actuarial calculations than are applicable to general sickness service. Confining the scope to employed groups insures certain standards of health and income and reduces sales and collection expense.

Such schemes seem to afford temporarily, at least, regular financial support to the hospital, it is claimed that they will tend to reduce fluctuations in the use of

services and to distribute the burden of cost among a large number, thereby reducing the load on individuals. If hospital standards are maintained, a fairly high grade of care is assured.

Such schemes provide a method of payment of the costs of hospitalization for many patients who might otherwise be objects of charity and a burden on the resources of the hospitals.

Some of its present and prospective defects are that

To a large extent such schemes are being installed as a result of a "tactics of desperation," in which hard-pressed hospitals are seeking "any port in a storm." This is a situation in which hasty action is apt to create institutions and vested rights and relations the future effects of which may be far different from present expectations. Such plans need careful consideration based on investigation and comparison of experiments now under way. Examination of some of those already in existence and others in process of adoption gives ample evidence of the lack of such investigation and preparation.

The adoption of such a plan by a single hospital or a group of hospitals, in a locality, creates a division within the hospital field and the medical profession. By creating an artificial monopoly through salesmanship and through compulsion by employers, "unfair competition" is exerted on those hospitals outside the scheme. This situation encourages the formation of rival groups and such undesirable forms of commercial competition as solicitation, underbidding and consequent deterioration of service. It also destroys freedom of choice of physicians and hospitals for as large a section of the population as are induced to become members or certificate holders.

All such plans tend to lessen the control of county medical societies over medical practice and thus to decrease the effectiveness of the most important form of professional control of standards and ethics, while at the same time it increases the influence of lay commercial interests.

Even with all the safeguards of the British system, most of which are absent from American schemes, the question of control of hospital management of lay organizers of contributory schemes is becoming troublesome. Does any one believe that, once a promoting organization, perhaps of nation-wide scope, has through a system of contracts gained control of a large share of the market for hospital service, it will hesitate to use that power to influence or control hospital management?

Such plans tend to extend hospital care beyond its natural scope. Patients who would ordinarily be cared for by a family physician at home will more often insist on going to the hospital where they feel they have already paid for care. Baylor University Hospital found in its early experience that teachers used the hospital privileges during vacation for rest and the treatment of ailments neglected during the teaching term. This is an indication of a tendency that has disrupted actuarial calculations in many European systems of health insurance. When any form of service is paid for in advance, there is a desire to secure the benefits. Consequently, not only have morbidity rates steadily increased under all such systems but, whenever the medical services and cash benefits are not separated, great pressure is brought on physicians to certify to sickness so that the cash benefits may be obtained. It is probable that a similar pressure will be exerted by contributors to hospital insurance on attending physicians to secure hospital certification. Should this

tendency develop, it would invalidate the calculations, none too accurate at present, on which schemes of hospital insurance are based, and also tend to create some of the conflicts between patient and physician that have had such evil results in systems of general health insurance. Where there is a choice of hospital, if the rates paid are such as to leave a surplus, the hospital may be inclined to encourage overhospitalization as a source of income.

These plans make the hospital a "preferred creditor" over the physicians and surgeons. Unless the contract and the salesmen make it emphatically clear that the services of the physician require additional payment, many patients will be led to believe that their contributions cover all expense during hospitalization. Experience has shown that hired salesmen soliciting contributions from firms and individuals may not only neglect to point out any such restrictions but may seek to give the impression that *all* medical care is covered by the contributions or monthly payments.

The employment of salesmen, especially on commission, which is a feature of most plans, introduces all the elements of commercial competition, including some that are considered "unfair" even in business. Such plans depend on securing contracts for future sales from a large section of the market for medical services and then using the monopoly so secured to fix the terms of such service. When this monopoly is further buttressed by group and employment compulsion, denying to the individual for some time in the future the right to select the form and source of his medical service, conditions are created closely analogous to those that have already been condemned in business by the Federal Trade Commission and the courts. Such a comparatively mild method of insuring future patronage as is offered by "trading stamps" has been forbidden by law in many states.

Reference has already been made to the dangers of misrepresentation when salesmen are employed. Practically all these plans issue some sort of advertising, usually in the form of circulars or pamphlets for general distribution. Such material invariably exaggerates the scope of the protection offered. In many cases the divergence between such advertising and the terms of the contract is greater than the Federal Trade Commission permits in business advertising.

The moment the sphere of commercial competition is permitted to invade the organization, direction and marketing of medical services, and especially if these functions are placed in profit-seeking commercial hands, the whole history of medical practice has shown that deterioration in ethics and service inevitably follows. Rival schemes fight for survival by lowering payments for professional services, by more flamboyant advertising and exaggerated promises and by giving inferior service.

If payments are made direct to the hospital or if the funds are held in open bank account by the commercial organization promoting the scheme, there is, in some plans, no security that the scheme is sufficiently sound financially or the funds so safeguarded that in case of failure the insured who had contributed for future care might not be left without recourse. This is especially true when a scheme is conducted either by a hospital or by a separate agency without proper safeguards being set up to insure the safety of the funds.

Every new social arrangement tends to become a nucleus of much wider developments and to establish

institutions, customs and vested interests having an influence far beyond the immediate intentions of the founders. This will almost certainly be true of hospital insurance. The first tendency, already developed in several schemes, is to extend the scope of the scheme from hospitalization to general medical care. There are some especially undesirable features about the extension of a scheme planned for hospitalization, often managed by profit-seeking promoters and with no control by organized medicine. If general medical care for low-paid workers is to be placed on an insurance basis, it certainly should not be introduced incidentally through plans organized for other purposes and in ways hostile to the best considered opinions of the organized medical profession.

There are a number of legal questions that do not seem to have been sufficiently investigated and have not yet been passed on by the courts. Can a hospital chartered "not for profit" enter into a scheme which, as do some of those offered by promoters, promises considerable profits? Do these schemes constitute insurance? If so, will they come under the various laws and regulatory bodies set up for control of insurance? The legal provisions of the different states vary widely on this point and certainly should be examined by any hospital proposing to enter into such a scheme. The exact legal obligations incurred by the hospital through the contract with the member or certificate holder lack clear definition and interpretation. In view of the relation to insurance and to the prohibition of some closely analogous forms of "unfair competition," the exact responsibilities assumed under such a contract have not yet been clearly defined. Such arrangements make the physician certifying to the need of hospitalization a part of the contract and create relations in some ways different from those existing when such a contract does not exist.

The broad effect of all such plans is to shift the burden of hospital support from philanthropy and good will to assessment of low-paid workers. One of the selling points made by promoters of such plans is that the surplus received from contributions constitutes a profit or may be used to meet the expense of indigent care. It is also urged that many previously free bed wards may be changed to income-producing space. Is it entirely ethical for an institution to utilize philanthropic gifts to build such free ward beds and then use them for producing income or profit? This question may be purely academic at the present moment, but will it remain so in the future?

Restriction of the scope of service to the employed means that a worker who contributes to such a scheme for years becomes ineligible for its benefits the moment he loses his job. If the loss of his job is due to failing health, he loses his protection just when most needed.

Confining the scope of the service to employed wage-workers leaves a large section of the population most in need of hospital care without protection, a feature that in other countries has led to a demand for all-inclusive, compulsory governmental action. Is the pattern being created by the present hospital schemes one that could be followed by such an extension without the introduction of great harm to the medical profession and the public?

These present and projected defects which characterize most of the current schemes for group hospitalization constitute a violation of the principles of professional conduct and the practice of medicine which for thousands of years have proved their fair-

ness, soundness of doctrine and faithful adherence to the best interests of the public. Taking advantage of a temporary financial exigency, certain commercial interests have selected that portion of medical care which is easiest to sell and are endeavoring to create a mass production market from which a considerable profit will accrue to the promoters.

A pertinent question which has been avoided by the promoters of hospitalization schemes is: Does the public need at the present time an increased amount of hospital care or will it benefit more from a greater amount of medical care in the home? Whichever way the question is answered, disregard of the principles that should govern all agencies equipped to render medical care is certain to result in an ultimate lowering of the quality of medical care. The physical capital in medicine, in whatsoever form it may exist, must always remain the instrument wielded by the personal skill and knowledge and must ever conform to an undepreciated standard of medical values. Anything that separates the mental capital from the working tools and institutions of the profession is sure to prove destructive to the medical profession and injurious to the public.

535 North Dearborn Street

COMMENTS ON THE INTERNSHIP

W C RAPPLEYE, M.D.
NEW YORK

The importance of practical experience in the training of physicians has been recognized since the beginning of history and in every part of the world. The earliest efforts to control medical licensure and education developed requirements for this phase of the preparation of the physician. The edict of Frederick II in 1224, which was merely an elaboration of that promulgated by Roger II of Sicily in 1140, provided that no physician could be licensed until he had completed the examinations conducted by the masters at Salerno and had practiced under a recognized physician for one year.

The medical training in Great Britain and France from the beginning has been developed around clinical clerking and other practical experience in the wards of the hospitals and in district dispensary teaching in such institutions as the University of Edinburgh. The long period of training in Sweden, Holland and Denmark is designed to permit ample experience for students in the care and treatment of patients. The apprenticeship method of training in the earlier days of this country produced physicians almost entirely by means of practical experience.

When the medical schools in this country were organized, many of them were created as independent enterprises in contrast with the development of medical training in the hospitals of England and France and in the universities of Germany, Holland and other continental countries. In many places the classes were very large. Elsewhere the clinical facilities were inadequate. In most instances the teachers were practitioners who were busy with their own vocation. The cost of conducting adequate laboratory teaching made it impossible in most places to provide a sound preparation in the basic sciences. For these various reasons, the training in most of the medical schools was largely didactic and

theoretical in character. The internship was designed to correct the lack of practical bedside instruction and to afford a period of supervised experience in the care and treatment of patients.

The internship has now come to be widely regarded in this country as a part of the basic training for the practice of medicine, as attested by the facts that about 95 per cent of recent graduates voluntarily take a hospital experience of one year or longer, that seventeen states now require the internship as a prerequisite for admission to the licensing examinations, and that a similar number of medical schools in the United States and Canada require it before granting the degree of Doctor of Medicine.

The type and arrangement of the hospital period should not be standardized, however. It is important that the educational features of the internship should not be rigid or uniform for all hospitals but should provide a variety of opportunities of high quality adapted to the educational needs, previous preparation, and life programs of different individuals. The present trend of medical education, in common with that of all phases of higher education, is toward adapting the training to the needs, capacities, interests, preparation and plans of the individual student rather than providing a uniform, rigid discipline that is essentially identical for all students. The internship is only a part of the whole scheme of medicine and, as such, several kinds of internships will best meet the requirements of different students. All, however, should aim to round out and complete the earlier period of preparation in the medical course proper and should be arranged to facilitate the continuity of that training.

There are 696 hospitals, representing 221,174 hospital beds and offering 6,261 internships, which are approved by the American Medical Association (1932). The mere fact that a hospital is a good hospital does not necessarily mean that it provides a satisfactory internship, for the latter requires an interest on the part of the staff in the training of the young physician and an ability to provide him with a satisfactory educational experience.

Unfortunately, a considerable number of the hospital services are used inadequately for educational purposes and some internships are merely devices for securing free resident services in the hospital, largely for the benefit of the institution and the staff. Furthermore, the best appointments are usually secured by the superior students from the better medical schools. The less well trained students may be further handicapped by an inferior hospital experience.

The preliminary period of hospital experience should be the most important phase in the development of a competent physician, for it provides the opportunity for the student to apply his knowledge to practical problems under the direct supervision of qualified physicians and to obtain graduated responsibilities for the actual care and treatment of patients. It is highly important that every effort be made to improve the educational content of the hospital training and to relate it more soundly to the medical course and to the professional needs of the young physician.

Much discussion has arisen in recent years regarding the most desirable type of hospital service. In a number of states, attempts have been made to prescribe the content and time requirements of various parts of the experience. It is unfortunate that the internship as an educational experience should be standardized and regulated in this manner. The type of service is not

nearly as important as the opportunities that are provided for the right kind of training

A properly conducted rotating internship can be made a rich educational experience, but usually the periods assigned to each department are so short that a student has opportunity to obtain only the most superficial contact with the subject matter of each division. He is given very little opportunity to benefit by the assignment to any single service. This serious defect of a plan which tries to present most of the clinical fields in a short period or which aims merely to provide a kaleidoscopic presentation of cases may actually destroy in students the careful, thoughtful approach to complicated clinical problems which is the aim of the earlier training in the medical school. One objective of that training is the development in the student of sound methods and habits of study which will provide him with a permanent intellectual and professional equipment for his entire career. An internship which thwarts the development of those sound methods and habits of study cannot serve the best interests of the profession, the student or the public.

The usual "straight service," on the other hand, is apt to be unsatisfactory for the student who is going into general practice, and frequently it is not well articulated with the basic medical course. Such a service often does not provide a sufficient range of experience with the usual disorders, accidents and disabilities seen in the community.

Some of the straight surgical appointments probably do more damage than good when they encourage the recent graduate to do surgery before he is really prepared in judgment, skill and experience to do it properly or safely. It is well known that the popularity of some of these services is due to the opportunities provided for the interns to do major surgery. Contact with and watching expert operators is liable to create the impression that surgery is relatively easy and largely a matter of operating room technic.

Neither the usual short rotating service, which provides a hurried, superficial experience in many departments, nor the usual long straight service, which provides an experience in a single field, meets the needs of most students. The so-called mixed service has been developed in an attempt to provide a sufficiently long and intensive experience in a single subject, such as medicine, and a shorter period in another field, such as nonoperative surgery, pediatrics or obstetrics. They have the merit of flexibility and can be made to fit the educational needs of the student. They permit him to improve and extend his knowledge and skill in methods of diagnosis and treatment and to become acquainted with a sufficient range of the usual diseases and accidents to make him a reasonably safe and competent practitioner. They provide the most satisfactory preparation for general practice or for further training in a limited field of practice than do most rotating or straight services.

If a better control of surgical practice in this country is to be secured, those in charge of surgical internships have a peculiar opportunity and responsibility. It does not follow for a moment that all surgical internships are unsatisfactory. Some of them which lay particular emphasis on diagnosis, preoperative and postoperative care, and nonsurgical therapy, and less emphasis on specialized technics, provide an educational experience which is thoroughly satisfactory. The surgical internship, however, should not aim to produce a surgeon

The experience and training which aim to do so should be secured in postgraduate education, particularly through the development of resident services of sufficiently long duration to allow a physician to obtain a thorough training in the field.

A number of centers are now planning or have created programs of graduate training in the several clinical divisions (general surgery, urology, neurologic surgery, the head specialties, orthopedic surgery, pediatrics, psychiatry, obstetrics and gynecology), admission to which is based on completion of a previous internship. This is a move in the direction of advanced preparation for practice in the special fields. It is a part of the important trend to require all those who desire to limit their practice to a specialty to have had an adequate preparation in their limited field. Time will not permit a discussion of the place which this phase of training will or should play in the creation of a register of specialists in each state. As these graduate phases of medical practice and education become more clearly defined and more widely recognized, we shall probably see a definite modification of the internship in special departments of general hospitals and in special hospitals. In some centers already the trend is toward abolishing internships in single services (surgery, pediatrics, obstetrics) and toward the development of residencies as a part of graduate instruction, admission to which is based on a previous general internship.

If the internship is to be successful as an educational venture, some individual or group on the staff of the hospital should be responsible for seeing that opportunities are actually provided for the intellectual and professional development of the student, and that the work of the intern is properly supervised by responsible members of the staff, particularly in regard to the discussion of cases, differential diagnosis, proper treatment, and the use of the laboratory, library and other facilities in the study of patients.

It is highly desirable that the student during his hospital period should assume more personal responsibility for the care of individual patients and become familiar with various elements in the environment, the home, and the everyday activities of the patient, in order that he may secure a more intelligent understanding of these factors which are known to be so important in practice.

Only about 10 per cent of patients are hospitalized. The great majority of sick persons are not obliged to go to a hospital. Outpatient services should be used as much as possible to assist the intern in becoming acquainted with the more common illnesses and with the wide range of social and economic factors which are often important in diagnosis and treatment. As part of his educational development the intern should be given freedom for reading and should be required to use the library as well as the laboratory in working up cases and should be expected to attend staff meetings, clinical conferences, autopsies, the readings of roentgen examinations, and consultations, and to participate as fully as his training permits in the care and treatment of patients.

The internship occupies a position in the educational plan between the basic course, in which significant changes are now being made, and the now rapidly developing fields of postgraduate education, in which a number of major developments are now in process. If the development of the hospital period of training is to be sound and of the greatest value, medical faculties should take a more active interest and responsibility

in shaping the hospital opportunities as an essential part of the whole program of medical education, of which the medical course, the internship, graduate training for the specialties, and postgraduate instruction of practitioners are only different phases

RENAL FUNCTION IN ARTERIAL HYPERTENSION

LAURENCE B ELLIS, M D
AND
SOMA WEISS, M D
BOSTON

It is being increasingly recognized that hypertensive cardiovascular disease is not a primary disturbance of the kidneys. It terminates much more commonly by cardiac failure or cerebral apoplexy than by renal failure. Nevertheless, it usually affects the kidneys to some degree and occasionally enough to produce renal insufficiency and uremia. The importance of determining the state of the renal function in this condition is therefore evident. In a previous paper¹ it was concluded that an adequate analysis of kidney function was possible from the results obtained from the following three tests: (1) an examination of the urine for albumin, casts and cells, (2) a determination of the degree of glomerular filtration by an urea or creatinine clearance test, (3) a test for tubular reabsorption by determining the ability of the kidney to concentrate urine. In the present study these tests have been applied to a group of patients suffering from arterial hypertension but with no clinical evidence of renal failure, in order to gain as much information as possible regarding the nature of the physiologic and pathologic changes that occur within the kidney in association with arterial hypertension of varying duration. In addition, a group of eight patients with glomerulonephritis were similarly studied mainly for the sake of comparison with the twenty-four primary hypertension cases.

The terminology employed by Volhard and Fahr² is used here. The renal lesion occasioned by primary arterial hypertension would be classed by these authors under the head of nephrosclerosis. It corresponds to the condition called arteriosclerotic Bright's disease by Addis³ and by Van Slyke⁴. The studies reported by these investigators were made on relatively advanced cases as compared with our cases.

MATERIAL USED

Twenty-four cases of arterial hypertension were studied. The systolic blood pressure varied between 175 and 260 mm of mercury, with an average of 212. The diastolic pressure varied between 95 and 150 mm of mercury, with an average of 116. The majority of the patients had been known to have high blood pressure for at least two years. With the exceptions to be noted, all were ambulatory and showed no evidence of cerebro-

vascular, cardiac or renal failure at the time of examination. Patient 19 had dyspnea on moderate exertion, patient 2 had suffered a hemiplegia as a result of a cerebral hemorrhage seven weeks previously, and patients 12 and 24 had had cerebrovascular accidents many months prior to the studies, from which they had largely recovered. Patients 6 and 15 had had several cerebral vascular crises. Patients 6, 7, 17, 19, 20, 21 and 22 were classed as cases of malignant hypertension. Of these, patients 7, 17 and 22 subsequently died, six months, four months and one month, respectively, after the studies were performed, and autopsies confirmed the clinical diagnoses.

There were eight patients with glomerulonephritis. Of these, cases 26, 27 and 28 were of the acute type. Cases 25 and 29 presented subacute nephritis, and cases 30, 31 and 32 were chronic. Patient 25 was the only one who showed marked edema. All three patients with the chronic lesions subsequently died. Patient 25 was discharged with essentially an unchanged state of health, all the others recovered apparently completely or were discharged clinically well and with only slight evidence of residual kidney damage.

METHODS OF INVESTIGATION

Urinalysis was carried out in the routine clinical manner. The extent of albumin present was recorded from \pm to $++++$, representing amounts from the slightest detectable trace to a large amount. The number of casts and red and white blood cells present per high power field in the sediment of a centrifugated fresh specimen was noted. No further attempt was made to quantitate the abnormal formed elements.

The percentage excretion of phenolsulphonphthalein two hours and ten minutes after its intramuscular injection was studied.⁵

The dilution-concentration test that was employed consisted in having the patient drink 1,500 cc of water at 8 a. m., and no more fluid was given for twenty-four hours. Urine specimens were collected at hourly intervals for four hours after the water had been drunk, at two hourly intervals during the rest of the day and in one specimen at night.

In all cases the urea clearance test was performed according to the technic of Moller, McIntosh and Van Slyke.⁶ An attempt was made to obtain a maximum clearance in each case by having the patient drink at least 400 cc of water each hour during the test and during the hour preceding it. In spite of this in a few instances the urinary excretion fell below 2 cc per minute, and the standard clearance was therefore calculated. Values below 75 per cent of the theoretical normal were considered to represent an abnormal decrease in functioning kidney tissue.

The creatinine clearance was performed in accordance with the technic described by Rehberg.⁷ Three grams of creatinine with 600 cc of water was fed to the subject at least an hour and a half before the test period. A calculated filtrate of less than 100 cc per minute was considered to represent abnormally low function.

RESULTS IN PATIENTS WITH HYPERTENSION

Urea Clearance—Although in only ten patients were the values for the urea clearance within the normal limits (75 per cent or more), nevertheless in nine other patients the results of this test were from 63 to 71 per cent of normal

Creatinine Clearance—In general, the degree of reduction in the creatinine clearance tended to parallel that found in the urea clearance. In cases 2 and 21 the urea clearance value was relatively higher than the creatinine clearance, in five cases (11, 15, 16, 17 and 18) the creatinine determination gave normal values when the urea clearance was slightly reduced

Summary of Results of Renal Function Tests in Twenty-Four Patients with Hypertension and in Eight Patients with Glomerulonephritis

Sub ject	Urine Examination			Maximum Concen- tration, Specific Gravity	Clearance		Phenol sulphon phthalein Excretion, per Cent in 130 Min	Blood Urea Nitrogen, Mg per 100 Cc

Concentration-Dilution Tests—An inability to concentrate the urine to a specific gravity of at least 1.020 was considered definitely abnormal. A maximum concentration of 1.025 or greater was taken to mean normal concentrating power. When the concentration fell between 1.020 and 1.025, the results were considered doubtful, although probably representing some decrease in concentrating power of the kidney.

A comparison of the concentration test with the urea clearance showed that on two occasions the concentration test gave definitely abnormal figures and twice the test suggested that probably the kidney was impaired when the urea clearance was within normal limits.

Conversely, twice, when the urea clearance was slightly reduced, the concentration test gave quite normal results. In all seven of the remaining cases in which the urea clearance was slightly low, the maximum specific gravity was between 1.020 and 1.025. In four of the five patients in whom the urea clearance test

was less than 60 per cent of normal the concentration test showed a distinct inability to concentrate the urine, and in the fifth the maximum specific gravity was 1.020. It is evident, therefore, that there was a tendency for reduction in concentrating power to parallel reduction in the urea clearance test.

The creatinine concentration in the urine samples collected for the dilution-concentration tests was determined and a blood creatinine determination was made in most of the cases. No creatinine was fed. From this the creatinine concentration index was calculated (concentrated urine creatinine — concentrated blood creatinine).

As pointed out previously,¹ there is reason to believe that the calculated glomerular filtrate without feeding creatinine gives results that are too low. However, when the maximum creatinine concentration index attained in any given case was compared with the maximum concentration of total solids, as indicated by the specific gravity, there was a tendency for a relationship between the two.

Every case in which the concentration index was at least 200 showed also a maximum specific gravity of 1.025 or higher, and every case in which the concentration index was less than 200 showed inability to concentrate the urine to a specific gravity of 1.025.

Urine Examination—Only one patient showed marked albuminuria in the absence of evidence of definite diminution of kidney function by the other tests. With increasing kidney damage, however, albuminuria as well as slight to moderate cylindruria and microscopic hematuria became a more prominent feature of the laboratory examinations.

Phenolsulphonphthalein Excretion—The phenolsulphonphthalein excretion was definitely impaired in only one case. This is in accord with the conclusion of others that this test as usually applied is of little value in detecting renal impairment until at least 50 per cent of the renal reserve has been lost.

Blood Urea Nitrogen—None of the patients studied showed levels for the blood urea nitrogen outside of what is usually considered the normal range. Until the urea clearance fell below 50 per cent of normal there was no correlation between the degree of impairment of renal function as measured by the urea clearance test and the height of the blood urea nitrogen. When the urea clearance fell below 50 per cent of normal, however, the blood urea nitrogen tended to rise. The average blood urea nitrogen in the patients with renal function above 50 per cent was 11 mg per hundred cubic centimeters, and in those below 50 per cent, 23 mg.

RESULTS IN PATIENTS WITH GLOMERULONEPHRITIS

The studies on the eight cases of glomerulonephritis were included to contrast the results obtained in this type of renal disease with those occurring in arterial hypertension. The most striking difference was in the urinary observations. Except when the disease was latent, albuminuria and hematuria were prominent features of the urinary picture, even though the total degree of glomerular filtration (as measured by the urea or creatinine clearance tests) was well maintained.

In four of the eight cases of glomerulonephritis (patients 26, 27, 28 and 29) the creatinine clearance test was found to give relatively higher results than did the urea clearance. In these patients this may have been due to an increased permeability of the tubular cells to urea, resulting in an excessive diffusion of urea back into the blood stream.

CORRELATION BETWEEN RESULTS OF RENAL TESTS
AND CLINICAL RESULTS IN HYPERTENSION

Age of Patients—A relationship between the age of the patients and the degree of renal impairment did not exist

Symptoms—There was no correlation between the nature and extent of the symptoms and the degree of renal damage. This is to be expected, since in none of the twenty-four cases of arterial hypertension was renal insufficiency present at the time the studies were made, and impairment of kidney function does not give rise to striking symptoms until renal failure occurs.

Height of Blood Pressure—There was a definite tendency for the degree of renal damage to increase with increase in the arterial blood pressure. This was especially true for the diastolic pressure. It would be unwarranted, however, to attribute any direct relationship between these two results. This is because the patients with excessive hypertension were those in whom widespread and marked vascular damage was present, who probably suffered from a diminished functional reserve of many organs. Moreover, in some of the individual cases presenting marked hypertension the renal reserve was within normal limits, so that it would be unjustified to draw conclusions as to the state of the renal function from a consideration of height of the blood pressure alone.

Duration of Disease—In a chronic condition such as arterial hypertension, which may exist for many years unrecognized and without symptoms, it is obviously impossible to correlate accurately the duration of the disease with the degree of the renal lesion. In the present series the known duration of the disease ranged from a few weeks to thirteen years. Patients 11 and 16, who have been under observation for thirteen and eleven years, respectively, had comparatively little impairment of renal function.

COMMENT

Correlation Between Physiologic and Morphologic Changes and the Clinical Manifestations—The facts elicited in this investigation are in accord with the known changes that occur in the kidneys in the early stages of hypertension. The renal lesion in this condition is due primarily to vascular changes, particularly in the glomeruli. Histologically, the lesions of the kidney are unevenly distributed and are of different degrees of severity. There is evidence⁸ suggesting that the earliest changes in the kidney as in other organs are of functional rather than of organic nature. A constriction of the efferent portion of the vessels of the glomeruli⁹ may well be the earliest change, which may result in increased capillary pressure and decreased blood flow in the glomerulus in which this constriction occurs. The rather characteristic change with thickening in the basement membrane¹⁰ and eventual shrinkage to complete sclerosis develops later. As has been pointed out by McGregor,¹⁰ at the time these changes involve some of the units of the kidney, others remain entirely normal. She observed a certain degree of quantitative correlation between a ratio of the percentage of normal glomeruli to the percentage of glomeruli

with characteristic changes in the basement membrane on the one hand and the reserve functional capacity of the kidney and uremia on the other hand. Thus, while the size and gross appearance of the kidney and a qualitative analysis of the microscopic changes fail to reveal a clear-cut relation between kidney structure and function, when such analysis is performed on a quantitative basis the correlation promises to be more definite. Histologically, the tubules are less involved than the glomeruli. This may be due to the fact that ischemia in the tubules with normal or low capillary pressure and with lack of stagnation may be less damaging to them than the same degree of ischemia is to the glomeruli in which high capillary pressure and back pressure dilatation of the capillaries exist.

Little attempt has been made to interpret in terms of physiology this irregular and scattered abnormality of the kidney units, so obvious from the histologic study of sections. It is apparent, however, that there must be considerable variation in the functional activity of the individual renal units within the same kidney. In the unit with a partially or completely sclerosed glomerulus, the blood flow is probably slow or may be completely stopped, while at the same time in the structurally normal or slightly damaged units the blood flow is increased considerably. One of us (S W)⁸ has demonstrated in a case of malignant nephrosclerosis with hypertension that the total blood flow through the kidney was considerably increased although a histologic study indicated that only 27 per cent of the glomeruli were normal. Of the remainder, 28 per cent showed changes characteristic of arterial hypertension, 32 per cent, changes that occur in glomerulonephritis, and 13 per cent, complete sclerosis.

As pointed out in a previous paper,¹¹ the concentration test measures the ability of the individual tubule to absorb water. This reabsorbing ability may be impaired, not only as a result of direct structural damage to the tubular cells themselves, but also as the result of conditions whereby excessively large amounts of glomerular filtrate pass rapidly down the tubules. In view of the fact that, with the progressive changes which occur in nephrosclerosis, many of the glomeruli are completely sclerosed, one may conceive of a situation in which half of the glomeruli are obliterated by the vascular disease but the remainder are comparatively unaffected. Under such circumstances, the normal glomeruli must greatly increase their individual filtration in order to maintain within normal limits the total amount of glomerular filtrate formed. However, this filtrate would be passing down half the usual number of tubules and the reabsorption of water would be hampered. Such a mechanism may have taken place in cases 6 and 8, in which the glomerular filtrate was normal although the maximum concentration was distinctly impaired. The frequently observed dilated tubules of units with normal glomeruli are probably the result of increased filtrate flowing with increased pressure and velocity through these tubules. Fremont-Smith and his co-workers,¹² on the basis of Cushny's¹³ theory, have considered theoretically the effect on tubular reabsorption of filtration through many or few glomeruli and with varying numbers of glomerular capillaries open.

However, there occurs in a certain number of instances an impairment in concentrating power due to actual damage to tubular function itself, secondary to the vascular changes. This is especially striking in the cases reported showing severe renal damage. In such stages the histologic structure of the tubules suggests this functional concept.

The great variation in the results of the renal function tests in patients with arterial hypertension is by no means as confusing and haphazard as it appears. When the functional tests are correlated with the known structural changes that have been observed in the kidneys of patients who have suffered from hypertension, the scattered and variable involvement of vessels of different renal units explains satisfactorily the results obtained with the clinical tests.

The Value of the Tests Used—In clinical practice, the value of the three tests used in this study comes especially from performing them at repeated intervals on the same patient. It is only by repetition that an estimate can be obtained as to the rapidity with which the vascular disease is causing impairment of renal function, and thus a prognosis can be arrived at.

Although the urea or creatinine tests are relatively sensitive in detecting early renal damage and they express absolute function of the kidney, in clinical practice it is frequently impracticable to carry out those tests which require elaborate laboratory technic and meticulous accuracy. For practical clinical purposes, in most early cases, provided there is no water retention, a carefully conducted concentration test when correlated with an examination of the abnormal constituents of the urine will furnish a fairly accurate index of renal reserve. If it is desired to carry out as complete an examination of the renal condition as is possible at present, and to separate the glomerular from the tubular functions, it is necessary to perform a test for glomerular filtration as well.

The term "essential hypertension," as identifying a hypertensive state of the body without impairment of the kidney function cannot be applied rigidly. This is illustrated by the fact that, in the present study, practically all the cases of arterial hypertension showing kidney impairment detected by the methods used would have been classified as "essential hypertension" in the past.

SUMMARY AND CONCLUSIONS

1 In twenty-four cases of arterial hypertension without clinical signs of cardiac or renal failure, and in eight cases of glomerulonephritis, three types of tests of renal function were used: the usual urinalysis, urea and creatinine clearance tests, and concentration-dilution tests.

2 In ten of the cases of hypertension the urea clearance test gave normal results, in nine there was a slight reduction, and in five it was markedly lowered.

3 Creatinine clearance tests, in eighteen of the same cases, was normal in thirteen instances, slightly reduced in two, and markedly reduced in three. In general, the outcome of the urea and creatinine tests tended to give parallel results.

4 In the twenty-two cases in which the concentration test was performed in the patients with hypertension, the maximum specific gravity of the urine was above 1.025 in six instances, ten times it fell between 1.020 and 1.025, and in the remaining six cases it fell below 1.020.

In only two cases did the concentration test show a definite lowering without a marked reduction in the urea or creatinine clearance tests.

For practical purposes, in most cases a carefully conducted concentration test is as sensitive an index of renal impairment as the urea and creatinine clearance tests.

5 Marked albuminuria or hematuria was uncommon in hypertension unless great limitation of function was detectable by other tests.

6 The results of this study have been analyzed in accordance with the filtration-reabsorption theory of renal physiology and have been correlated as far as possible with the histologic changes in the kidney, known to occur in hypertension.

7 There was a trend for the degree of impairment of renal reserve to parallel the height of the arterial blood pressure, particularly the diastolic pressure. There was no correlation to be made between the degree of renal damage and the age of the patients, the symptoms or the known duration of the disease.

DUPUYTREN'S CONTRACTION

SUMNER L. KOCH, MD

CHICAGO

A surgical condition seen rather often, but by no means as frequently as injuries of the tendons and nerves of the hand, or contractures due to a loss of covering tissue, is the idiopathic contraction of the palm and fingers with which is associated the name of the man "whom living all admired but whom few loved and no one understood," the founder of clinical surgery in France, Dupuytren.

Concerning it there are two essential facts that the surgeons should know: first as regards the pathologic manifestations and, second, the treatment.

From the very beginning of the disease a cord is felt on the palmar surfaces of the finger and hand, which is drawn tighter when an effort is made to straighten the fingers. The palmar fascia is in a state of thickening, contraction and tension, and from its lower portion something like cords proceed to the sides of the affected fingers.¹

With reference to the treatment

The fascia should be dissected out at once. An incision should be made through the skin over the whole of the contraction, and if the integument is tolerably soft and thick it should be turned off on each side so as to expose the fibrous tissue, which should then be carefully taken away. The utmost care should be taken to avoid the nerves and blood vessels at each side of the finger, and if the operation can be satisfactorily effected without opening a sheath or touching a tendon so much the better.²

These two brief paragraphs, which constitute the gist of the subject, are taken almost verbatim, the first, describing the pathologic lesion, from Dupuytren's *Leçons orales*, published in 1832, and the second, out-

From the Department of Surgery, Northwestern University Medical School.

Part of a paper on "Surgery of the Hand," read before the Boston Orthopedic Club, April 11, 1932.

lining the treatment, from Sir William Fergusson's System of Surgery, first published in 1842

It is an interesting commentary on the inconsistency of our profession that, alert as we are to every new discovery in medical science, we often completely neglect the careful investigations of those who have preceded us, sometimes by many years. The majority of the patients with Dupuytren's contraction who have

heavy object, the irritation associated with the constant use of golf clubs, and the frequent shifting of gears in driving a car. Not uncommonly a considerable interval, two or three or even more years, has elapsed between the injury and the onset. Furthermore, although patients with bilateral involvement frequently have ascribed the onset of the disease in one hand to a definite injury, they have been at a loss to explain its appearance in the other hand, or perhaps they have not been aware that it was already present in the other hand.

Similar reasoning might apply to the possibility of "gout" or "rheumatism" or a distant focus of infection as the important etiologic factor. In none of our patients have we been able to determine a definite relation between infection in some other part of the body and the development of the contraction. Careful questioning as to their past history and careful physical examination have not revealed a definite clue as to a possible relation between infection and Dupuytren's contraction. They have suffered from tonsillitis, dental infection and "rheumatism" just as has the patient who comes to the hospital because of a hernia, an acute appendicitis, or a hallux valgus.

The most significant fact, in my judgment, with reference to the development of the disease is the frequency with which one is able to elicit a history of similar involvement in other members of the family, and in the males particularly. The hereditary factor, frequently mentioned by earlier writers, assumes increasing importance if one questions patients carefully concerning their forebears. Among our patients with Dupuytren's contraction there have been eleven physicians, the daughter of a physician and the nephew of a physician. Of these thirteen patients, ten have given

Fig. 1—Dupuytren's contraction of left hand. A, B, C before operation. D, E, F result three months after operation.

come under my care have consulted many different medical men and have frequently been told that the condition involved the flexor tendons and that if any operation was carried out the function of the hand would probably be lost.

Space does not permit me to review in detail the various theories concerning the etiology of the disease or the many interesting facts concerning its incidence and life history. My associates and I³ attempted a few years ago to record them as carefully as possible. As was indicated in that paper, three theories have been presented to explain the thickening and gradual contraction of the palmar fascia which form the essential pathologic change: local traumatism or infection, infection in some other part of the body, a congenital predisposition to the disease. Approximately one half of the patients who have come under our observation have ascribed the onset of the condition to a single definite injury of the hand or to continued irritation associated with constant use of the hand in some specific occupation or sport. We have not felt, however, that the evidence furnished a reasonable basis for considering trauma as the important etiologic factor. The traumas to which the development of the contracture have been ascribed are identical with those to which each one of us is constantly subjected—a slight penetrating wound, a baseball injury, a bruise from the impact of a

Fig. 2—Type of incisions used in case illustrated in figure 1.

a history of a similar or, perhaps, of a more extensive contracture in other members of the family.

In considering the treatment of Dupuytren's contraction, it is difficult to improve on the paragraph quoted from Sir William Fergusson's System of Surgery. We have laid constant stress on certain factors: the correct choice of incision, the use of a bloodless field secured with the help of a known degree of constriction (the blood pressure manometer), complete removal of

³ Kanavel, A. B., Koch, S. L., and Mason, M. L.: Dupuytren's Contraction with a Description of the Palmar Fascia. A Review of the Literature and a Report of Twenty-Nine Surgically Treated Cases. Surg. Gynec. & Obst. 45: 145-190 (Feb.) 1929.

hopelessly involved skin, and wide removal of the palmar fascia well beyond the obviously involved area, exacting care in the dissection to protect the digital nerves and blood vessels, the use of a free full thickness graft if skin edges cannot be brought together without tension, careful hemostasis, last, but far from least, careful technic at every stage of the operation to insure asepsis and wound healing by primary union.

Two of these factors deserve an additional word. The incision used most frequently in our earlier cases was a longitudinal one along the line of the contracted cord. With the use of such an incision it was not always possible to reach nodules that had developed in the radial half of the palm, or to secure healing without the development of a longitudinal scar which required some time to become soft and inconspicuous. In later years

tissue, and as the cord contracts the nerve is not uncommonly displaced to one side or the other as much as a fingerbreadth. Unless the nerve is followed with care and dissected free from the fibrous tissue that surrounds it before any of the fibrous tissue is excised, it is almost impossible to avoid irreparable injury of this important structure, with subsequent anesthesia and trophic disturbance of the skin of the affected portion of the finger.⁴

In February, 1929, when our paper referred to was published,³ we had operated on twenty-nine patients with Dupuytren's contraction. Since that time we have been able to add eighteen new cases to this group and to observe for a longer period those previously operated on. Our results have constantly improved, as we have used greater care to remove all the involved fascia, to avoid trauma of skin flaps and of digital nerves and vessels, and to leave nothing undone in the preoperative preparation and operating room technic that would help to protect the patient from wound infection, and so help to insure primary healing of the operative wound.

54 East Erie Street.

AN OPERATIVE TREATMENT FOR CORNS

WALTER I. GALLAND, M.D.
NEW YORK

The treatment of the common corn, which is one of the most widespread of the minor ailments affecting the feet, has been almost entirely ignored by the medical profession, and most sufferers have been exclusively treated by practitioners of chiropody. The common treatment is the paring down of the hypertrophied epithelium or the application of various types of keratolytic pastes, plasters, collodion paints and protective pads. These remedies are at best palliative and frequently, in spite of the adoption of proper footwear, the corn persists and continues to cause not inconsiderable discomfort. The palliative treatment of corns is adequate in perhaps the greater number of cases, but occasionally the condition is intractable and renders the wearing of any type of shoe painfully uncomfortable. Indeed, the irritated corn, which compels the individual to hold the foot in a strained attitude in order to avoid the unpleasant friction with the shoe, may be the primary causation of a severe chronic foot strain with all the accompanying sequelae of that condition.

Basically, a corn is not dissimilar to a bunion save in those variations which are predicated on location, size and anatomy of the underlying joint. The clavus, or common corn, consists of more than the keratinized skin which is pared off by the chiropodist. This cornification is but the result of a chronic irritation and although this irritation is probably initiated by improper footwear, there are certain structural changes in the toe underlying the corn which favor the continuance of the cornification. As in a bunion, there is a definite hyperostosis, which takes place at the interphalangeal

Fig. 3—Dupuytren's contraction of both hands (patient of Dr. Emory M. Porter of Providence, R. I.). A, B, C, D, E, F, G, H, right and left hands before operation, I, J, K result six months after operation on right hand, at time left hand was operated on. (The result of the operation on the left hand, according to the patient's statement, is equally good. Photographs have not yet been secured of the left hand after operation.)

we have utilized more often the incision indicated in figure 2. By continuing such an incision proximad along the ulnar side of the hand, excellent exposure of the fascia in the palm can be obtained. The transverse limb of the incision permits the removal of fascia on the radial side of the hand as far as the index finger. Such incisions, moreover, heal readily and with minimum scar formation since they do not cross the normal flexion creases of the palm.

Another factor, protection of the digital nerves also deserves added emphasis. In the fingers, as Mason showed, the digital nerves lie between the two layers of the digital fascia. As these two layers fuse and become converted into the thick fibrous cord that is so frequently the outstanding feature of the disease, the nerve becomes completely surrounded by firm fibrous

4 In view of the difficulty that one encounters in dissecting the digital nerves involved from the surrounding fibrous tissue, even when one has adequate exposure and a bloodless field it is surprising that subcutaneous division of the affected fascia should still be recommended yet Davis stated (Davis, A. A. The Treatment of Dupuytren's Contracture. A Review of Thirty-One Cases with an Assessment of the Comparative Value of Different Methods of Treatment, Brit. J. Surg. 19: 539-547 [April] 1932) that "as the results from even the most major operative procedures are far from satisfactory, the minor operation of multiple subcutaneous fascial division should be adopted, and repeated if necessary, in the average patient of the hospital class." From the orthopedic services of Dr. Charles H. Jaeger, Lenox Hill Hospital, and Dr. Harry Finkelstein, Hospital for Joint Diseases.

joint margins and forms a definite though minute prominence, which may frequently be palpated by careful digital inspection. Once this exostosis has been produced, the skin is constantly subject to frictional irritation between the shoe and this bony prominence. It is quite obvious that under such conditions there should be a tendency toward the formation of a bursa between the skin and the osseous projection. In the so-called inflamed corns, this bursa may reach not inconsiderable size, and, as in the case of bunions, may become definitely infected. The pain that is produced in the corn arises largely in this bursal structure. I have removed a bursa underlying a corn on a fifth toe when the bursa measured 1 by 1.3 cm and its removal reduced the size of the small toe by fully 25 per cent.

The bursal nature of this structure has been demonstrated by pathologic examinations of tissues removed in operations in such cases. The following reports verify the bursal character of this tissue, which interposes itself between the small exostosis and the corn.

Dr Henry L. Jaffe of the Hospital for Joint Diseases reported

The gross specimen consists of a fragment of soft tissue. This is a small bursal sac. The entire specimen was embedded. Microscopic section shows a sac, the lining of which is in places intact and is synovial-like in character. In places it shreds out indefinitely as necrotic tissue. The wall is edematous with very mild round cell infiltration. Diagnosis: Bursa.

The following report is by Dr F. W. Bullock of the Lenox Hill Hospital:

The specimen, received in solution of formaldehyde, consists of a rectangular fragment of tissue, opaque white in color, firm in consistency, measuring 1.3 by 0.7 by 0.2 cm, designated "tissue from little toe of left foot." Microscopic examination shows fibrous tissue, parts of which are compact, while other parts are loose and edematous. This tissue is rich in small thin-walled vascular spaces, most of which are empty. These spaces are irregularly distributed and usually occur in groups. They are often surrounded by collections of small round cells and in certain regions the inflammatory cells show a more diffuse distribution. One surface of the fragment is concave and is covered with a thick layer of fibrin, in the meshes of which are a moderate number of polymorphonuclear leukocytes. Diagnosis: Chronic bursitis or tenosynovitis. No evidence of tuberculosis.

It is obvious from the foregoing that in order to effect a cure of a particularly painful corn the underlying pathologic condition must be removed. It should not be forgotten, however, that frequently hammer toes too will predispose to corns on the apexes of prominent interphalangeal joints. These deformities may be of a primary nature and may be caused by any of the numerous conditions that can lead to the production of a claw foot. In other cases, however, the hammering deformity may be secondary to the irritation of improper footwear and may thus be attributed to the same basic factor as that which produced the corn itself. It is obvious, therefore, that these basic deformities of the toe must also be corrected in order to avoid the reformation of such corns. The following operative procedure for the radical cure of corns has been devised and has proved satisfactory in every respect.

The toe is anesthetized with 2 per cent procaine hydrochloride. It is most advisable to use a regional anesthetic administered at the base of the toe, so that the area of the corn should not be infiltrated with the anesthetic as this renders the dissection of the bursa difficult. After the foot has been properly prepared, the

keratinized epithelium is removed from the corn by means of a sharp curet. If the operator begins to dissect with the curet around the margins of the corn, he will be able to find a natural plane of cleavage between the keratinized and the normal skin, and the entire superficial structure of the corn can be removed *en masse*. The skin is again iodized, and the area of the corn is surrounded by a semielliptic incision outlining a flap with the base proximally placed. This flap is dissected carefully, so that it will include only the skin. The bursal structure underlying the flap will now be found overlying the interphalangeal joint and above the extensor tendons. The bursa is dissected and removed. The extensor tendons are now displaced laterally or medially, and the joint margins are inspected. The bony prominences can usually be easily delineated or can be found by digital inspection. The prominence is largely cartilaginous, on account of the proximity to the joint structure, but also contains a considerable bony component. With a small chisel this tiny exostosis is removed, and the contiguous articular margins are smoothed out so as to present no irritating irregularities to underlie the skin. The wound is closed with silk sutures, which may be removed at the end of a week.

The patients are usually able to walk about immediately after the operation, provided they wear a shoe liberally cut out. Some patients have sufficient pain to keep them off of their feet one or two days.

In the healing process it is usual to find a considerable exfoliation of keratinized skin over the operated area in spite of the fact that a large portion of this cornified structure has been removed with the curet. At times this is so pronounced that it at first appears that the corn is returning, but in the course of ten days this mass is completely exfoliated and leaves behind a satisfactorily normal skin surface. A rather acute trichophytosis developed in one case of my series following the operation. This infection most probably originated from an area of trichophytosis that was overlooked prior to operation. It caused considerable irritation to the operated area and was uncomfortable for the patient. Accordingly, it is to be recommended that all such fungal infections be thoroughly treated prior to operation in order to avoid this unpleasant complication.

The soft corn is susceptible to precisely the same operative treatment. This type of clavus differs from the indurated corn only on account of the location between the toes. The moisture that gathers in this place subjects the keratinized skin to a macerating influence, and the cornification of the skin is modified in the form and consistency. However, the bursa and exostosis are always present and must be eradicated to cure the condition. On account of the absence of the heaping up of keratinized skin it is not always necessary to curet off this structure, as it will exfoliate in toto after the removal of the underlying pathologic condition.

CONCLUSIONS AND RESULTS

1. Painful corns are pathologically similar to bunions and can be effectively cured by operative means.

2. The operation described eliminates the pathologic sources of irritation by removing the bursa and the exostosis underlying the corn.

3. The operation causes a minimum of discomfort to the patient.

4. In the series of corns on which I have operated, the results have been extremely satisfactory, and no recurrences have been noted to date.

1085 Park Avenue.

AN HEREDITARY ARTHRODYSPLASIA
ASSOCIATED WITH HEREDITARY
DYSTROPHY OF THE NAILS

JOHN W. TURNER, M.D.
ATLANTA, GA.

The condition that is being reported here as an hereditary arthrodysplasia is a disorder that is transmitted from parent to child, that causes deformity of the different joints interfering with their function and that, so far as it has been possible for me to determine, has never been reported previous to this report, which is based on a study of two families in which thirty-five of seventy-nine persons are affected.

It seems advisable to bring this condition to the attention of the medical profession, as the disorder in some instances causes deformity sufficient to compel the afflicted one to seek relief and as the deformity simulates other conditions with which it may be confused.

About five years ago the ninth individual in the fourth generation of the first family came to me as an obstetric patient. I noticed that she suffered from hereditary dystrophy of the nails and that her knees appeared flat when her legs were extended and angular when the legs were flexed on the thigh. The true significance of the condition was not realized at that time. A short while later one of her sisters consulted me because she frequently fell when running. Her knees also appeared flat when extended and square and angular when flexed and it was very hard to locate the patellae, which could not be found on the anterior surface of the knees. The tubercle of the tibia stood out prominently with the patella absent from its customary position. The ankles were thick, the malleoli being unusually large and contrary to the normal type, the internal malleoli larger than the external. The longitudinal arch of the foot was apparently less developed than normal, a slight degree of flatfoot being present.

Fig. 1—Occurrence of hereditary arthrodysplasia associated with hereditary dystrophy of the nails through five generations of first family.

Fig. 2—Occurrence of hereditary arthrodysplasia associated with hereditary dystrophy of the nails through four generations of second family.

The shoulders showed a marked prominence of the acromial end of the clavicle, the appearance being similar to that presented after dislocation of the acromial end of the clavicle. However, in the deformity due to arthrodysplasia the step down from the acromial end of the clavicle was downward and forward to a prominence caused by the head of the humerus. Apparently the glenoid cavity of the scapula was well in front

of a line drawn downward from the anterior margin of the acromial end of the clavicle, and the head of the humerus with its muscle group stood almost in bas relief. The patient was unable to extend fully the arm at the elbow, and the carrying angle was increased. The internal condyles were unusually prominent on the inner side of the elbows. The wrists showed no very marked variation from normal. It appeared that there was a slight elongation of the carpal region, and the ends of the ulnar were barely noticeable when the hand was pronated. The fingers could be hyperextended at the metacarpophalangeal and interphalangeal joints.

Roentgenograms of the different joints showed deformities which may be considered characteristic. The picture of the shoulder girdle shows a scapula that is undersize. The coracoid process appears small. The acromial process is small and does not come forward above the head of the humerus. The head of the humerus appears smooth, the classic features of this bone being underdeveloped, the greater tuberosity being less great, the bicipital groove less deep. Examination of the elbow (fig. 4) shows a thickening of the lower extremity of the humerus in the anteroposterior diameter and a hump on the lower three inches of its posterior surface, giving a forward and outward inclination to this portion of the shaft. This forward and outward inclination is probably a factor in the increased carrying angle and the inability fully to extend the elbow. The internal condyle is larger and more prominent than normal and the capitellum is smaller than normal. The head of the radius is small. The picture of the wrist shows a marked concavity formed by the alinement of the posterior surfaces of the carpal bones. The metacarpophalangeal and interphalangeal joints appear to present no appreciable variation from normal.

In observing the patient there appears to be no appreciable abnormality of the hip or pelvis, but the roentgenogram (fig. 5) shows an increase in the angle between the neck and the shaft of the femur, the neck being more in line with the shaft than is normal. There is also an increase in the normal concavity of the external surface of the ilium, giving the crest the appearance of an outward flare in its posterior half.

In looking at a picture of the knee (fig. 6), the patella is located with difficulty, a rudimentary patella

Fig. 3—Patient showing absence of patellae, prominence of internal malleoli, low arches, increase of carrying angles at elbows, inability to extend elbow fully, and prominence of internal condyles. The right knee has been operated on.

being found high and wide on the outer side of the femur, both in flexion and in extension of the knee. The inner condyle and inner tuberosity of the femur are unusually prominent, playing a disproportionate share in the formation of the knee joint. This is so marked that the inner articular surface of the tibia shows a decided compensatory inclination downward and inward and the internal border of the tibia runs in an exaggerated curve upward and inward, giving the upper extremity of the tibia the appearance of leaning inward. The tubercle of the tibia stands out prominently. The upper extremity of the fibula is small and not well developed. The ankle seems well formed, although the malleoli appear larger than normal, the internal malleolus being much increased in size. The superior surface of the os calcis is convex anteroposteriorly in its posterior half and not concave, as is normal. It does not present the well marked lip normally found at the posterior superior border of the bone. The neck of the astragalus is not well marked, the trochlear surface being more in line with the head than is normal and not sitting well above it.

The dysergasia of the knee joint seems to inconvenience the afflicted person more than that of any other joint. Two of the members of the first family (fig 1) came to me because they frequently fell when running, the leg giving way at the knee. One of these suffered such marked inconvenience that operation for the purpose of anchoring the quadriceps tendon was advised. She was admitted to Scottish Rite Hospital and operated on with good result.

In the first family every member showing dystrophy of the nails suffered also from arthrodysplasia, twenty-six of thirty-nine persons being affected. In the second family (fig 2) twenty-seven of forty-one persons suffered from dystrophy of the nails, but only nine

Fig. 4—Elbow showing thickening of humerus, large internal condyle and small capitulum and head of radius.

suffered from arthrodysplasia, these not being specifically shown in the genealogical chart.

Hereditary dystrophy of the nails of the toes and fingers is a comparatively rare disorder, but not so rare that most physicians have not seen several cases. Jacobsen¹ in 1928 reported a family in which this

anomaly of the nails was associated with congenital alopecia and, in a review of the literature at that time, found reports of four other families in which these defects were associated. Barrett² reported a family in which these two conditions were associated with the occurrence of an hereditary hypothyroidism, this family being included in the group of five reported by Jacobsen. Tobias³ reported a family showing heredi-

Fig. 5—Pelvis, showing outward flare of crest of ilium and increase in angle between shaft and neck of femur.

tary dystrophy of the nails unassociated with any other defect, and Thompson⁴ reported another.

The degree of the disorder of the nail varies from almost total absence of the nail to a nail that is scarcely distinguishable from a normal nail except that it is thinner. The thumbs are usually most affected, the condition becoming gradually less marked across the hand toward the little finger. The typical dystrophic nail presents a small normal appearing base that is, however, much thinner than normal and that gradually disappears about halfway down the nail bed, allowing the fleshy end of the finger to turn backward over the nail. When the extreme condition is present, it appears that the nail has been removed from the digit and not reproduced. The defect renders the digit affected almost useless for picking up pins and other thin objects.

Trophic disorders of one sort or another are frequently found in those individuals to whom the term constitutional inferiority is applied and Barrett² and other authors have referred to the association of mental deficiency with this anomaly of the nails. The association of disorders of other derivatives of the ectoderm has been reported and ichthyosis, keratosis palmaris, hypertrichosis, alopecia, and premature or abnormally late eruption of the teeth have been referred to as coexisting stigmas. Indeed the mental deficiency usually noticed in patients suffering from this dystrophy

¹ Jacobsen A. W. Hereditary Dystrophy of the Hair and Nails, J. A. M. A. 90: 680 (March 3) 1928.

may be considered as evidence of further involvement of ectodermal structures. The defects with which dystrophy of the nails has been associated in all previous reports have been found in ectodermal derivatives exclusively. The two families included in this report have had no associated defect of any derivative of the ectoderm but have shown a rather marked disorder of portions of the skeletal system, a derivative of the mesoderm.

The hereditary arthrodysplasia reported has been observed only in association with hereditary dystrophy of the nails. It appears to be transmitted in accordance with the laws that govern the inheritance of dominant characteristics, as described by Mendel. In the first family the same factor appears to govern the inheritance of the two disorders. In the second family it is evident that there are two different factors involved, as many members having defective nails show no defect of the skeletal system. In neither family does this arthrodysplasia appear independent of the dystrophy of the nails, consequently it may be deduced from these cases that the factor for dystrophy of the nails must be present for the factor for arthrodysplasia to be active. It is probable that whenever these two factors are present in the chromosomes, the individual will show arthrodysplasia. This would be the most simple explanation. On

Fig. 6—Knee, showing small patella, large inner condyle and inner tuberosity of femur, prominence of tubercle of tibia, and exaggerated curve of upper third of internal border of tibia.

the other hand, it is possible that both factors are present in every individual showing dystrophy of the nails but that a third factor is present also in those who do not show the arthrodysplasia and that the third factor has a repressive action on the factor for arthrodysplasia or on the interaction of the two. Certainly there is demonstrated in these cases the interaction of factors in man as described by Mendel and as demonstrated in plants and in color inheritance in the feathers of certain fowls. This is to me an interesting feature of these two conditions.

The fact that the degree of the arthrodysplasia may vary considerably from the well developed case, as described, to the case showing a minor degree of dysplasia of the knee alone or to the case which shows a well developed dysplasia of one knee and an apparently normal mate to it suggests that this condition may

be inherited according to the so-called mosaic inheritance. However, Adam⁵ has suggested that mosaic inheritance does not necessarily preclude the operation of mendelian factors, which are usually understood to carry a whole or none feature. Other authors have treated such variation at length.⁶

In this short sketch of the features of these patients' joints which appear as variations from the normal, it has been my endeavor to point out those which are most striking. No doubt, the entire skeletal system is affected and those who are more familiar with the normal and better observers than I will point out more surely and skilfully and describe more accurately these and other variations. It has served, if this condition has been called to their attention as a distinct clinical entity.

Clinical Notes, Suggestions and New Instruments

DERMATITIS FROM THE USE OF HEXYLRESORCINOL SOLUTION S T 37 ACQUIRED SENSITIVITY

CLAUDE L. CUMMER, M.D., CLEVELAND

The discovery of the cause of dermatitis is desirable from the patient's standpoint so that it may be avoided not only to expedite recovery but chiefly to prevent recurrences. To this end, reporting of instances is important when the previous record of offending substance has not been made.

Hexylresorcinol solution S T 37 is a widely advertised antiseptic, in general use by the profession and the public, but when the patient whose history follows was seen in 1931 I was unable to find any reference in the literature to possible irritating effects. In March, 1932, Templeton and Lunsford¹ reported six cases of stomatitis and cheilitis produced by S T 37 toothpaste, supposed to contain hexylresorcinol solution S T 37. They were unable to demonstrate which ingredient was responsible but suspected either altered or unaltered hexylresorcinol solution S T 37. All their patients reacted to contact tests for cutaneous sensitivity to S T 37 toothpaste, but apparently only two of them reacted to pure hexylresorcinol solution S T 37. Templeton and Lunsford had used hexylresorcinol solution S T 37 in full strength for many patients in their daily practice for over a year without any instances of dermatitis.

In May, 1931, I saw a patient with a severe cheilitis and also a dermatitis of the right hand and certain other portions of the body, which was shown by contact test to be due to S T 37 toothpaste, but in this case, as in some of Templeton and Lunsford's, the contact test to the pure hexylresorcinol solution S T 37 proved negative.

Because of the absence of any reports of dermatitis due to the solution itself, I feel that the following should be published for record.

A white married woman, aged 60, seen, April 18, 1931, through the courtesy of Dr. E. B. Rhodes of Cleveland, complained of a dermatitis involving the right ankle, the face, the neck, and the upper part of the chest, as well as inflammation of the lips and mouth. Examination showed injection and edema of the buccal mucosa, especially marked on the right side. The face, neck and upper part of the chest were bright red. In these areas the skin was edematous, especially over the eyelids, and was practically covered with pin-point to pin-head sized vesicles. On the right ankle was an approximately circular patch about 3 inches (7.5 cm.) in diameter showing similar changes.

The patient stated that she first noted a small spot on the ankle which she regarded as a mosquito bite. Hexylresorcinol

⁵ Adam: Principles of Pathology, vol. I.

⁶ Morgan, Sturtevant, Muller and Bridges: Mechanism of Mendelian Heredity, chap. II, p. 38.

¹ Templeton, H. J. and Lunsford, C. J.: Cheilitis and Stomatitis from S T 37 Toothpaste, Arch. Dermat. & Syph. 25: 439-443 (March) 1932.

solution S T 37 and a brand of thymol iodide (U S P) powder had been applied, and the inflammation had become progressively worse. About a week later, pyorrhea appeared around a right molar tooth. Fearful of a peridental abscess, she applied hexylresorcinol solution S T 37 on a pledget of cotton. Soreness of the lip was observed two days later.

The patient was unwilling to accept the diagnosis of dermatitis due to hexylresorcinol solution S T 37, because this solution had been a household remedy which her family had used freely and she herself had employed without harm for a long time. However, she consented skeptically to the application of a patch or contact test, which was performed with the contents of a new bottle in an original package. When seen on the following day, the test area showed erythema and vesiculation, an eruption identical in appearance with that on the face, neck and leg. The entire trouble cleared up promptly with the application of cold compresses of diluted solution of aluminum acetate.

Obviously, the reaction to hexylresorcinol solution S T 37 was due to an acquired sensitivity, since the patient had employed the solution previously for some months without unfavorable results.

AN EASY METHOD OF REMOVING PLASTER CASTS

RALPH J. MALOTT M.D., SCOTTSBLUFF, NEB.

Essentially, this method consists in creating, at the time of application, free channels between the gauze or wadding and the plaster, enabling one to saw through the plaster with a gigli saw, along a predetermined line.

Waterproof paper tubules (soda straws or similar casings) are threaded on a stout cord or a flexible wire of considerable tensile strength and applied over the gauze or wadding surrounding the part to be covered by the cast. At intervals of no greater than 12 inches the tubules, with encased cord or wire, are looped outward for a slightly greater length than the proposed thickness of the plaster cast. These loops are passed through perforated gummed paper strips, which, attached to the gauze, maintain their position.

The line of cleavage of the cast is determined at this time and may be a straight line or may be laid to meet the exigencies of the individual case. This method permits the easy forming of windows in the cast for the purpose of dressing the soft parts, in any desired location or shape. Diamond shape or rectangular apertures are secured more readily, but windows approximating a circle may be formed by short segments of very obtuse angles.

After the tubules are placed as desired, plaster-of-paris bandages are applied in the usual manner for laying a cast, and wrappings are made to surround these extended loops, so that when the cast is finished, the loops will extend a short distance beyond the surface of the cast. Being flexible, they may be protected by a bit of adhesive plaster to prevent wear until the time of severing the cast.

To remove the cast or to split it for temporary removal, the gigli saw is attached, by means of the eye in the end of it, to the stout cord or flexible wire and by that means is drawn through the first segment to be severed. Care should be taken not to angulate the saw too greatly to obviate breakage. Each succeeding segment of the cast is cut in the same manner. The time and energy involved in removing even a very heavy cast by this means is materially reduced. In addition, there is no opportunity of harming the patient since the act of sawing is always from within outward. For reapplication, a smooth line of cleavage is secured and the patient is spared the anxiety of cuts or pricks as are occasionally experienced when the cutting is toward the body.

Embedding materials in casts to facilitate the removal is an old trick but has heretofore presented difficulties which made it a greater nuisance than it was worth as a rule. This suggestion works well in my hands and in the hands of a few confreres who have tried it out and it is both inexpensive and a time saver.

1513 Broadway

AN ATRAUMATIC TYPE OF SURGICAL NEEDLE

HERBERT M. ILL, M.D., NEWARK, N. J.

For the past few years I have been dissatisfied with the eye in the surgical needle because it necessitates doubling the catgut at that point, with the resulting resistance of pulling the catgut through the tissue. Therefore I have devised an atraumatic type of needle, which can be used repeatedly.

Making use of the fact that catgut swells in water, I thought of drilling a hole in the end of a needle just large enough to

Atraumatic type of surgical needle. A open end of needle for catgut, B swollen catgut as in needle.

admit the contracted catgut as found in the sterile ampule, and having irregularities in the sides of the wall to allow for swelling of the gut to form resistance from pulling it out. After considerable experimentation at the plant of the Driver Harris Company of Harrison, N. J., such a needle was perfected, and it has proved highly satisfactory. This needle is made for any size catgut desired, and any shape, with no greater diameter than eye needles. To remove the catgut from the needle, both are placed in 95 per cent alcohol or some other dehydrating agent for about ten minutes, thus rendering the catgut readily withdrawable. This makes the needle ready for another filling of catgut. This needle does away with the tearing of tissues made by the knuckle formed by the catgut through the eye of the needle. It can be used repeatedly.

188 Clinton Avenue.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
H. A. CARTER, Secretary

MILWAUKEE AIR FILTER ACCEPTABLE

The Milwaukee Air Filter is manufactured by the Perfect Corporation, Milwaukee. The manufacturer claims that this machine is an efficient, relatively silent, portable machine for forced ventilation with filtered air in offices, homes and hospital rooms and is recommended as an adjunct for the relief of hay fever and pollen-borne asthma. It can be installed in any 26 inch or wider lift-sash window and requires no screws, bolts or clamps to hold it in place.

Externally the filter looks like a trapezohedron. The top and the bottom are trapezoidal and the housing is made of sheet metal. The motor and the blower fan are mounted in the narrow end on rubber mountings to eliminate the vibration. The air is drawn in through the screen protected circular opening and is forced through the filter at the opposite and wider side of the machine. The housing is so shaped that it can be mounted in any standard lift-sash window, and an adjustable filter is provided to close up the space left by the difference in the machine width and the width of the window. The filter can be conveniently replaced. The filtering surface is greatly enlarged by a plate-like construction of the material. Two types of filter can be furnished. The A filter is highly efficient and of close-woven material designed to eliminate the pollen and is recommended in the treatment of hay fever. The B filter is a more open weave and passes a larger volume of air. The firm claims that the air capacity of the standard unit using the type A filter is 8000 cubic feet per hour established by anemometer readings. The manufacturer writes:

Its efficiency as rated by the Hill test which is the only yardstick for measurement of air filter efficiency recognized by the American Society of Heating and Ventilating Engineers is 97 per cent at a face

velocity of 325 feet per minute, and since the efficiency of this type of filter increases as the free velocity decreases, we feel safe in assuming that the filtering efficiency is greater than 97 per cent

The advertising literature appears to be reasonably free from unwarranted claims

In a Council test covering a period of two days, three slides were placed directly in front of a blast of incoming air for a period of twenty-four hours. Control slides were placed in an adjoining room in approximately the same position with reference to the window and on the same side of the house

Results of Tests

Date	9/7	9/8	9/11
Milwaukee Air Filter	2	No slide	3
Controls—adjoining room	57	29	19
Outdoor air	43	91	87
Temperature	61	62	71
Air volume	120 cu ft per min		
Power	about 40 watts		
Shipping weight	about 50 lbs		

The volume of air displaced was measured by means of a Tycos anemometer. It is recognized by the investigator that the Pitot tube would probably have registered a higher value. However, it is believed that the aforementioned value is relatively correct.

The Council on Physical Therapy declares the Milwaukee Air Filter acceptable for admission to the list of accepted devices for physical therapy

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH, Secretary

PHYLICIN NOT ACCEPTABLE FOR N N R

Phyllicin is the name under which the Bilhuber-Knoll Corporation presented for consideration by the Council a salt of theophylline calcium salicylate, stated to have the chemical formula $C_8H_8N_4O_2 + H_2O \cdot C_6H_5CO_2Ca + H_2O$. Previously the Council had recognized the name Theocalcin for the similar salt with theobromine, since it has the advantage of being less soluble than the official theobromine sodiosalicylate. In view of this the Council voted to recognize the name Phyllicin but at the same time modified its rule concerning proprietary names to exclude the possibility of again recognizing a distinct name for an unessential or slightly different modification of an article already included in New and Nonofficial Remedies. Subsequently the Council voted to accept the product Phyllicin, provided the A M A Chemical Laboratory reported favorably on the composition.

In its report the Laboratory showed that the product was essentially a compound of theophylline and calcium salicylate with an admixture of impurities. The Laboratory further reported that from a chemical point of view Phyllicin appeared to have no marked advantage over theophylline sodio-acetate-N N R, especially as regards greater solubility, thus excluding the possible therapeutic advantage found in the analogous case of theocalcin. The Laboratory emphasized the fact that Phyllicin was not a definite compound and that, if it were found otherwise acceptable, it should be described as a product containing certain substances as impurities or as the product of chemical reaction.

The Council declared Phyllicin unacceptable for New and Nonofficial Remedies as not presenting sufficient originality in itself or sufficient advantage over theophylline sodio-acetate-N N R.

The foregoing report of the Council's action on Phyllicin was transmitted to the Bilhuber-Knoll Corporation. After considerable correspondence, the firm had not presented the evidence of originality or of chemical and therapeutic advantage required for the acceptance of Phyllicin. The firm, moreover, expressed the intention actively to market the product. The Council, therefore, reaffirmed its rejection of Phyllicin for the reasons given in this report.

Committee on Foods

REPORTS OF THE COMMITTEE

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

SNOW KING BICARBONATE OF SODA (BAKING SODA)

DAIRY MAID BAKING SODA (BICARBONATE OF SODA)

Manufacturer—The Snow King Baking Powder Company, Cincinnati

Description—Packaged bicarbonate of soda (U S P)

Manufacture—Sodium bicarbonate fulfilling U S P requirements is purchased in bulk lots and packed in cartons. The sodium bicarbonate is manufactured by the ammonia-soda process. Carbon dioxide is pumped into a salt brine saturated with ammonia, sodium bicarbonate and ammonium chloride are formed by the reaction, and the sodium bicarbonate, being least soluble in the solution, precipitates out. The crude bicarbonate is separated from the mother liquor and dissolved in water, the ammonia present is steam distilled. Calcium and magnesium salts impurities separate out during this treatment. The solution is filtered, the filtrate is treated with carbon dioxide, which precipitates the sodium bicarbonate in a very pure form. The pure sodium bicarbonate is filtered from the mother liquor, dried and packed in barrels.

Analysis (submitted by manufacturer) —

	per cent
Moisture	0.3
Sodium bicarbonate (NaHCO ₃)	99.3
Total carbon dioxide (CO ₂)	52.2
Sodium carbonate (Na ₂ CO ₃)	0.4
Sodium chloride (NaCl)	0.003
Poisonous metals	none

Complies with all U S P analytic requirements

Claims of Manufacturer—Intended for baking, cooking and home uses of baking soda

SUNRISE BREAD (SLICED)

Manufacturer—Log Cabin Baking Company, Oroville, Calif

Description—A white bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p 817), prepared from patent flour, water, sucrose, shortening, powdered skim milk, salt, yeast and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standard for white bread.

ARBITRATOR PATENT FLOUR SELF RISING (BLEACHED)

Manufacturer—Saxony Mills, St. Louis

Description—A self rising flour containing a patent flour of soft winter wheat (bleached), calcium acid phosphate, baking soda and salt.

Manufacture—The ingredients are mixed in definite proportions in a batch mixer and automatically packed in cotton sacks.

Claims of Manufacturer—This self rising flour is designed for general home baking, especially cakes and biscuits.

VICTORY BRAND TOMATO JUICE

Distributor—New England Importation Corporation, Boston

Packer—Vincennes Packing Corporation, Vincennes, Ind

Description—Pasteurized tomato juice with a small amount of added salt, retains in high degree the vitamin content of the raw juice, the same as Alice of Old Vincennes Tomato Juice (THE JOURNAL, Feb 20, 1932, p 640)

HOSPITAL SERVICE IN THE UNITED STATES

TWELFTH ANNUAL PRESENTATION OF HOSPITAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

The annual census of hospitals, just completed by the Council on Medical Education and Hospitals for the period generally corresponding with the calendar year 1932, shows a considerable shift of patronage from the privately owned and controlled hospitals to those that are supported by taxation, in general a greater volume of work was done in hospitals than in the previous year

The census was begun late in 1932 and completed in February, 1933. The data from each hospital are for the last fiscal year preceding the census.

Although figures do not give an adequate picture of the work that is done by physicians, nurses, administrative staff, technicians and others in hospitals, yet statistics do help to form a conception of the extent

4 The 4,305 general hospitals, on the average, were 63.3 per cent filled. The 776 general hospitals run by government—federal, state and local—were 77.1 per cent occupied, while the 3,529 nongovernment general hospitals were only 55.9 per cent filled. All general hospitals had an average of 145,048 unoccupied beds, nervous and mental hospitals, 24,075, and tuberculosis hospitals, 10,154.

5 The total number of patients admitted to all hospitals in the United States for the fiscal year 1932 is 7,228,151. The average census of all hospitals was 808,445. The general hospitals alone admitted 6,303,573 bed patients.

6 The total number of births in all hospitals was 710,884.

HOSPITAL CAPACITY OUTSTRIPS POPULATION

The chart was made by placing on the diagram of increase in population since 1872 a curve representing the increase in capacity of hospitals for the same period. Capacity of hospitals since 1909 indicated by a black line is known. Before that shown by a dotted line it is unknown except for 50,000 beds established by census in 1872 (*Proceedings A. M. A.* 1873). Using the census figures for 1872, the estimate from that time to 1909 and census figures since 1909 the proportion of hospital beds to population has increased from one bed for 124—a sixfold increase in ratio. That building is outstripping population there can be no question. Data on which the chart is based are given in the text.

to which the care of the sick has been transferred to hospitals. A few of the many facts gleaned from the annual census of hospitals therefore, are mentioned in this article. A mass of information is given also in the list of registered hospitals farther on in this issue.

1 This year for the first time, the total rated capacity of all hospitals exceeds one million. There are 1,014,354 beds.

2 There are 6,562 registered hospitals, as compared with 6,613 for the last previous census.

3 There were 69,199 unoccupied beds in federal, state and local government hospitals and 136,710 in nongovernment hospitals—a total of 205,909 idle beds.

7 The furnishing of medical care and skill was done by 113,730 physicians, of whom 101,518 are on attending staffs, 2,018 are resident physicians, 7,757 are interns (including second year interns), and 2,437 are physicians serving as hospital executives.

8 There are 1,656 schools of nursing accredited by state boards of nurse examiners and 278 that are operating without that recognition, a total of 1,934.

9 There were 86,649 student nurses enrolled, 48,567 graduate registered nurses employed on a full time basis for nursing and 8,029 graduate nurses otherwise employed.

(Continued on page 892)

(Continued from page 887)

10 Among the 6,562 registered hospitals, there are 4,202 that have their own laboratories and 4,599 that maintain their own x-ray departments

11 Eleven hundred and twenty-nine hospitals have dental services with 2,395 dentists attending

12 Outpatient departments are claimed by 2,269 institutions. These departments served 8,186,811 patients, who made a grand total of 28,958,213 visits for outpatient service

13 The total patient-days in all registered hospitals was 295,082,425, as compared with 283,019,540 for the previous year

14 The average length of stay in all hospitals was forty-one days, in general hospitals it was fourteen days, the same as for 1931

15 Hospitals that were not found to merit recognition and therefore were refused registration numbered 527. They are, however, mainly small institutions, their total rated capacity being only 15,791, or a little over 1 per cent of the rated capacity of all hospitals

OCCUPANCY AND CAPACITY OF HOSPITALS

The total patients admitted to all government owned hospitals, including federal, state and local, rose from 1,833,078 to 2,049,553 in the period between this and the last previous census. Admissions in city hospitals

Percentage of Beds Occupied in Hospitals According to Types of Service

	1920	1930	1931	1932
General	65.5	64.7	64.4	63.3
Nervous and mental	95.7	94.8	94.0	94.9
Tuberculosis	82.7	85.5	85.0	85.4
Maternity	92.8	93.2	95.0	93.0
Industrial	54.0	53.0	48.1	47.4
Convalescent and rest	70.9	68.3	72.3	67.4
Isolation	30.1	32.7	38.0	40.0
Children's	65.9	67.0	66.9	67.8
Eye, ear, nose and throat	47.7	53.0	52.0	49.9
Orthopedic	80.2	83.5	78.1	79.4
Hospital departments of institutions	93.0	95.5	93.9	93.2
All other hospitals	74.0	78.3	69.2	74.0
Total hospitals	80.1	79.8	79.6	79.7

grew from 689,259 to 767,096, in county hospitals from 345,236 to 384,265, in state hospitals from 388,984 to 464,752, and in federal from 301,149 to 326,628. All departments of the government increased their hospital beds during the year. There is a falling off, however, in the number of beds under combined city and county control.

Nongovernmental hospitals as a group experienced a slump in business in the period covered by this census. The total admissions in all nongovernmental hospitals were reduced from 5,322,898 to 5,178,598, a loss of 144,300 patients. The heaviest losses apparently were suffered by the church hospitals, in which the number of patients admitted fell from 2,013,352 to 1,918,214, and in the individually owned hospitals, in which the number of admissions dropped from 459,184 to 428,256. The hospitals owned by independent hospital corporations admitted 2,712,662, as compared with 2,714,406 in the previous census.

Individually owned hospitals were reduced in number from 1,560 to 1,522, industrial from 135 to 118, and the fraternal from 76 to 74.

The number of hospitals in each of the several classifications, together with the number of patients admitted by each group and the average census of those patients is given in tables 1 and 2.

Table 1 gives the facts relating to hospitals classified according to the ownership and control, including both governmental and nongovernmental hospitals.

Table 2 gives the facts for the same hospitals grouped according to the type of service, such as general, nervous and mental, tuberculosis, and maternity hospitals. At the bottom of each table are summaries for each of the last six years, affording ready comparison.

Percentage of Beds Occupied in Hospitals According to Ownership or Control

	1920	1930	1931	1932
Federal	76.8	79.2	76.5	78.2
State	94.6	93.8	94.2	94.2
County	80.7	82.2	81.2	84.1
City	74.3	75.0	70.3	82.8
City-county	80.2	81.6	82.0	72.4
Governmental	88.9	88.8	88.7	89.8
Church	66.7	64.2	63.2	59.6
Fraternal	68.7	67.4	69.0	66.8
Industrial	54.4	53.1	48.2	47.7
Individual or partnership	54.2	51.7	48.7	45.6
Independent associations	65.9	65.4	64.3	61.3
Nongovernmental	64.6	63.2	61.9	59.2
All hospitals	80.1	79.8	79.6	79.7

The load carried by general hospitals is, for the most part, rather constant and regular. They decreased from 4,322 in 1927 to 4,305 in 1932, but the bed capacity in the same time increased from 345,364 to 395,543. There was a corresponding increase in the number of bassinets and the average number of patients. The number of patients admitted to general hospitals dropped from 6,321,861 last census to 6,303,573 this census.

Unoccupied Beds in Hospitals

	Unoccupied Beds (Average)		
	1920	1930	1932

Maternity	2,022	2,401	2,748
Industrial	3,180	3,229	3,191
Convalescent and rest	1,886	2,340	1,013
Isolation	4,745	5,118	4,456
Children's	1,857	1,841	1,724
Eye, ear, nose and throat	1,383	1,269	1,361
Orthopedic	1,175	1,045	1,363
Hospital departments of institutions	9,148	9,377	8,793
All other hospitals	2,364	2,107	1,689
Total unoccupied beds, all hospitals	180,367	192,487	205,819

With few exceptions, the total average percentage of beds occupied has not varied greatly from year to year. There has, however, been in recent years a decided shift of patronage from pay hospitals to non-pay hospitals. This shift has great significance for private hospitals because of the economic distress resulting from their lessened financial income.

Increases in hospitals for nervous and mental patients have been noted every year in these columns. Now,

in particular, special attention is called to increases in the number of these hospitals, their capacity and their patient population. A very thorough census of those hospitals was obtained by reports and by visits of representatives of the Council to nearly all of them.

Summary of Growth of Hospitals, 1909 to 1932

	Federal Hospitals		State Hospitals		All Other Hospitals		Total	
	Number	Capacity	Number	Capacity	Number	Capacity	Number	Capacity
1909	71	8,827	232	189,040	4,056	223,180	4,359	421,065
1914	93	12,602	294	232,834	4,650	287,040	5,037	532,481
1918	110	18,810	303	262,254	4,910	331,182	5,323	612,201
1923	220	53,860	601	302,208	6,009	399,045	6,830	755,722
1928	294	61,765	955	369,750	5,963	431,410	6,862	899,934
1931	291	69,170	576	419,282	5,740	485,663	6,613	974,115
1932	301	74,151	568	442,601	5,693	497,602	6,562	1,014,354

Additional facts on nervous and mental hospitals are given farther on in this article. The fact that the special survey was begun two years ago and recently completed will explain why the figures given under that heading vary slightly from those given in the column under nervous and mental in table 2, which was derived from the recently completed regular annual census of all hospitals.

The facts relating to capacity and the patient population in all other hospitals, such as maternity, industrial, convalescent and rest isolation, children's, eye ear, nose and throat, and orthopedic are readily noted in the accompanying tables. There are 136 maternity hospitals as compared with 178 six years ago, but in the same time the capacity has increased from 5,747 beds to 7,558 beds. Industrial hospitals have decreased both in number and in capacity as have also the hospitals for convalescence and rest, isolation, and eye ear nose and throat. Children's hospitals number fifty-eight, exactly as they did six years ago, but there has been a slight increase in their capacity.

MATERNITY SERVICE IN HOSPITALS

The total number of babies born in all hospitals for the period under survey was 710,884. In comparison with our last report there is an increase of 1,995, whereas the increase in the number of births in hospitals from 1929 to 1931 was at the rate of 45,000 a year. It would appear, then, that during the year 1932 childbirth was accomplished at home in some 43,000 cases which in normal times might have gone to hospitals. The number of babies born in maternity hospitals was one twelfth of the number in maternity departments of general hospitals. Among the 710,884 hospital births there were in general hospitals 651,757, maternity hospitals 54,688, industrial hospitals 3,579, and all other hospitals 860.

PHYSICIANS CONNECTED WITH HOSPITALS

Each hospital in cooperation with the census furnished the names of the physicians on the staff as well as those acting in other capacities. In cases of hospitals reporting their staffs for the first time the record of each physician is traced through the biographic file of the American Medical Association.

The accompanying table will show the number of physicians connected with hospitals in various capacities such as attending staff, resident physician, intern and superintendent, for each of the different states as well as in total.

It is found that a vast majority of all physicians accounted for here are graduates of class A medical schools or schools that were in good standing at the

time of graduation. The number of physicians on staffs, 101,518, is an approximation, based on a count of names of individual physicians furnished by hospitals, and elimination of duplicates. It was found in 1928 that there were 100 physicians for every 134 names returned on the staff lists in ten states where an actual count was made by the Committee on the Costs of Medical Care. It is on that basis that the present number of staff physicians, 101,518, has been obtained.

Physicians serving as administrators show an increase over last year from 2,346 to 2,437. Interns increased from 7,054 to 7,757. Among resident physicians there is an apparent decrease from 4,580 to 2,018, and this is due to the change in the method by which we are this year including as resident physicians those that are serving on an educational basis, and as staff physicians those residents that are hired for regular staff service.

HOSPITALS INCREASING SIX TIMES AS FAST AS POPULATION

A complete census of hospitals is available only back as far as the 1909 edition of the American Medical Directory. Before 1909, no satisfactory figures are available with the exception of a fairly complete survey by the United States Department of Education in 1872 reported in the Proceedings of the American Medical Association for 1873. That report shows that all hospitals in the United States in 1872 must have had a total capacity of around 50,000 beds.

Using that number as a starting point for that year, and apportioning the increase that must have taken place in each decade to make the 421,065 beds that were found in 1909 and then adding each annual census available since 1909, gives the best available knowledge on the increase of hospital beds by decades since 1872

Sixfold Increase in Use of Hospitals in Sixty Years, Ratio of Beds to Population, 1872-1932

Year	Hospital Beds	Population	Ratio Beds to Population
1872	50,000 (1st)	40,577,841 (1st)	1 hospital bed to 817 people
1880	45,000 (1st)	50,151,753	1 hospital bed to 590 people
1890	150,000 (1st)	62,947,714	1 hospital bed to 410 people
1900	250,000 (1st)	75,004,575	1 hospital bed to 304 people
1910	441,148	91,912,266	1 hospital bed to 208 people
1920	669,639	105,710,620	1 hospital bed to 158 people
1930	953,869	122,775,046	1 hospital bed to 128 people
1931	974,115	124,481,488 (1st)	1 hospital bed to 128 people
1932	1,014,354	120,187,630 (1st)	1 hospital bed to 124 people

Such has been the demand for hospitalization that while in 1872 one bed furnished the hospitalization demanded by 817 persons, in 1932 hospitalization existed at the rate of one bed for each 124 persons. Should the present rate of increase in hospital beds continue so to outstrip the rate of increase in population, overhospitalization is inevitable. On the whole, the country is without doubt already overhospitalized, although this may not apply to every community and certainly does not apply equally to all communities.

Total Patient Days and Average Length of Stay in Hospitals According to Control

	1920	1931	1932	Percent age of Increase 1920 to 1932	Average Length of Stay, Days 1931	1932

SCHOOLS OF NURSING

Among the 6,562 registered hospitals there are 1,934 schools of nursing, of which 1,656 have been reported as accredited by their respective state board of nurse examiners and 278 are reported as unaccredited. The total enrolment reported by all of the 1,934 schools of nursing is 86,649. In addition to these students in training, the whole hospital field makes use of 48,567 registered nurses on a full time basis for nursing only and 8,029 registered nurses for other duties. Information as to which schools of nursing are accredited was furnished as of January, 1933 by state boards of nurse examiners.

The number of schools of nursing has declined, but the number of students enrolled has increased, in recent years. In 1926 there were 2,155 schools with a total enrolment of 76,527 students. Even allowing for postgraduate students and affiliates in the enrolment reported in the present census, there still is an increase in number of students over 1926. The searching attention to the education of nurses and the consequent

realignment of ideals and standards, in recent years, are matters of common knowledge in the hospital field.

Among the 278 schools that are unaccredited by the state boards, there are a number of schools in the state institutions, particularly in Massachusetts, New York and Pennsylvania, which are giving courses that meet the requirements of the state departments under which those schools are operated, although they are not approved for the R.N. degree by the state board of nurse examiners.

The number of student nurses enrolled includes some postgraduate students, but the number of these was not ascertained. The number of student nurses enrolled also includes those enrolled in the 278 unaccredited schools. Figures here given regarding schools of nursing include schools that are affiliated with the accredited schools, they also include students in the affiliated schools.

PATHOLOGIC AND RADIOLOGIC SERVICES IN HOSPITALS

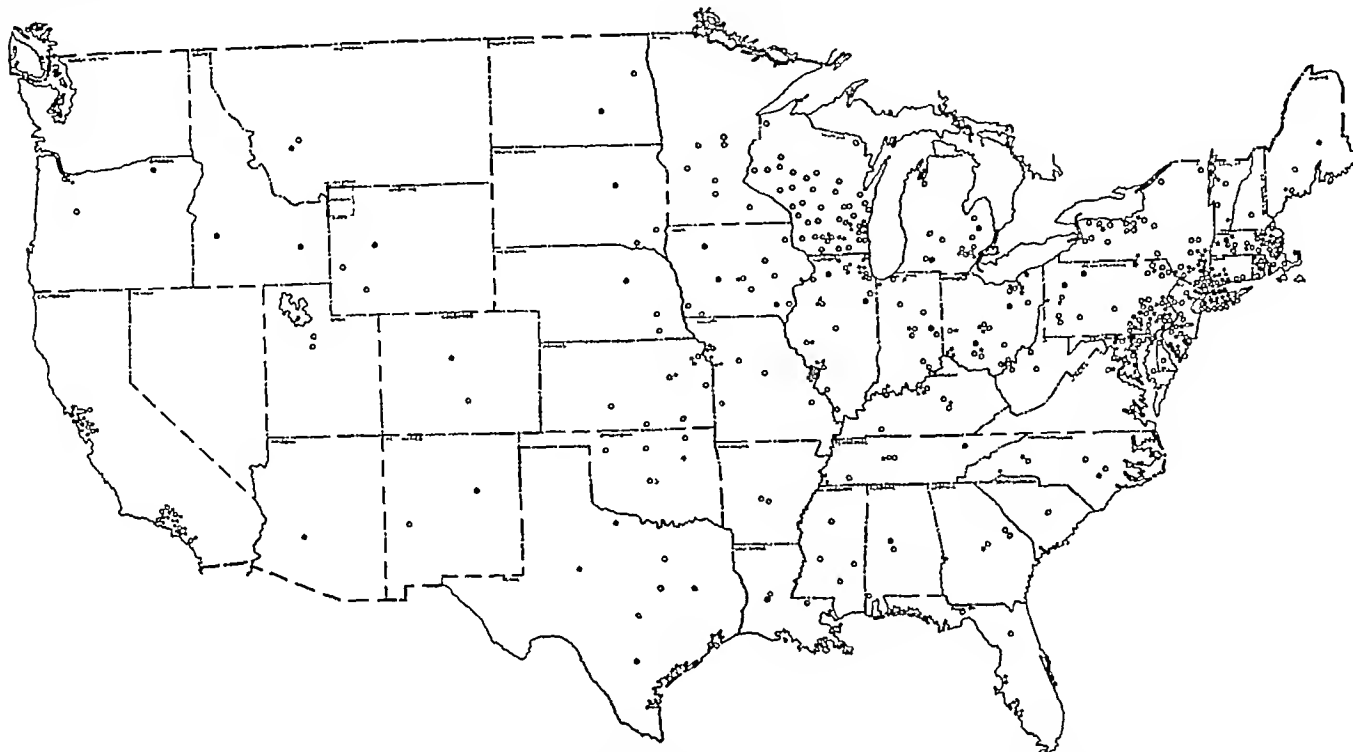

During the last ten years, the number of hospitals of all types having their own pathologic or clinical pathologic laboratory has increased from 3,035 to 4,202. The present census shows there are 1,313 hospitals that depend entirely on outside laboratories and 1,391 that use both their own and outside laboratories.

The number of x-ray departments in hospitals has increased during the past ten years from 2,841 to 4,599. Nine hundred and sixty-three hospitals have all their x-ray work done outside and 172 patronize outside radiologists in addition to radiologic services inside the hospital.

HOSPITALS FOR NERVOUS AND MENTAL PATIENTS

The largest number of special hospitals consists of those for nervous and mental patients. Six hundred and thirty-one institutions appear in the current register of hospitals and also in the separate list on page 901. Discrepancies which may appear between the figures

and patient population they represent nearly 50 per cent of the total. A proper interpretation of these figures must be based on an understanding of the kinds of institutions included in this group. Some are schools, others colonies. Of many others, large sections may be colonies or asylums not primarily concerned with hospital service but providing custodial care at a low rate for a term of years.

Map showing location of hospitals for nervous and mental patients in the United States. Government hospitals are marked by a circle and non-government hospitals by a star. (Map copyright by Rand McNally & Company.)

shown in the list of mental hospitals and those found in the general register are due to the fact that these two lists were compiled at slightly different times.

It will be noted that the number of nervous and mental institutions is less than 10 per cent of the total number of registered hospitals, but that in capacity

These 631 hospitals and related institutions report a total rated capacity of 427,315 beds and an average census of 445,867, indicating a serious overloading. Total admissions were 147,621, total discharges, including deaths, 117,693, showing an increase in the patient population of approximately 30,000.

COUNTIES HAVING HOSPITALS

The figures given here refer to counties in which there is a registered hospital under whatever auspices. It does not refer solely to hospitals supported by taxation and run by county commissioners. In several issues of the Hospital Number there have been statistics and maps showing the number of counties

Counties Having Hospitals

State	Total Counties		Counties Having Hospitals		Per Cent of Counties Having Hospitals

having hospitals located within their borders. It is not assumed that the county is the proper unit by which to measure hospitalization. The county, however, does come the nearest of any of our geographic subdivisions to representing the scope or extent of territory which can be served readily by a hospital in emergency as well as other cases.

It is obvious that many counties at present are not thickly enough populated to justify a hospital, and many are so located that already existing hospitals in adjoining counties meet the needs. In 1920 there were only 1,332 counties that had hospitals within their borders and there are now 1,882, a gain of 550 in the twelve years. In fact, 117 counties have had hospitals opened within them since 1928. A glance at the accompanying table headed "Counties Having Hospitals" shows what has been going on since 1920 and the amazing extent to which hospitals have been opened in counties not previously having them. This, without doubt, has had far reaching results in attracting and holding able physicians in those communities. Individual instances of this can be cited by the hundred. The census did

not bring forth any evidence that well prepared physicians avoid the small towns and rural communities and flock to the cities in any greater proportion than do those who are not so well prepared.

OUTPATIENT SERVICE

On the list of registered hospitals published in another part of this issue, hospitals reporting that they have an outpatient department are marked with a small circle. There are 2,269 hospitals, both general and special, reporting that they have an outpatient service. No definition or limitation was given as to what comprises an outpatient department.

It is found that, among those answering in the affirmative, there are 339 hospitals whose outpatient service amounted to less than 1,000 visits a year. This would leave 1,930 hospitals, or 29.4 per cent of all registered hospitals, that have an outpatient department of 1,000 visits or more a year. Nevertheless the total number of persons visiting the outpatient departments of hospitals during the year under survey corresponding mainly with the calendar year 1932 was 8,186,811, as compared with 6,750,388 five years ago.

Outpatient Service by States—Comparing 1927 and 1932

State	Number of Outpatient Departments		Number of Outpatients		Number of Visits by Outpatients	
	1927	1932	1927	1932	1927	1932

Wyoming	11	8	17,727	13,004	3,216	34,116
Totals	2,130	2,299	6,750,388	8,186,811	13,804,566	28,958,213

It is worthy of special note that during the same five year period the number of visits annually to the outpatient departments of hospitals increased from 13,804,566 to the enormous total of 28,958,213. The special significance of this figure in addition to its size is the fact that the outpatients made an average of more

than three visits each, whereas in 1927 they made an average of barely two visits each

The total number of visits were more than doubled during the last five years in thirty-three states. In four of these states, the number of visits increased over fourfold and in five states it increased tenfold or more in the same period. It is well known that attendance on the outpatient departments of hospitals always fluctuates with the business conditions throughout the country. Along with the increase of the amount of work done in outpatient departments there is evidence also of an increased use of that department for educational purposes, especially the training of interns and residents. It is there that the intern sees the kinds of patients and deals with those conditions which will come to him in his medical practice. The urgent importance of using the outpatient department to the utmost, for the instruction of interns, therefore, is obvious.

SIZE OF HOSPITALS

There has been a certain tendency to build somewhat larger hospitals, particularly for the care of mental patients, by states and for the care of indigents in large

Size of Hospitals (Based on 1931 Census)

Hospitals of What Size	Comprise What per Cent of All Hospitals	Admit What per Cent of All Patients	Have What per Cent of All Beds
Over 300 beds	8.20	23.63	59.58
From 201 to 300 beds	5.34	10.12	8.00
From 101 to 200 beds	12.73	24.40	12.46
100 beds and under	73.73	33.85	19.00

cities. On the other hand, there has been noted a decided tendency in the opposite direction—the building of many small hospitals in rural sections and towns to supply the demand for adequate hospitalization to each community. The resultant of these general tendencies has been a slight gradual increase in the average size of hospitals.

All hospitals of more than 300 beds capacity comprise 8.2 per cent of the entire number of hospitals and have 59.58 per cent of all beds and admit 23.63 per cent of all patients.

For the small hospitals, it is found that those of 100 beds and under comprise 73.73 per cent of the entire number of hospitals, have 19 per cent of all the beds, and admit 35.85 per cent of all patients.

HOSPITALS IN THE UNITED STATES POSSESSIONS

Statistics on the hospitals in the United States possessions show little change in the number of hospi-

Hospitals in United States Possessions

	Hospitals	Patients Admitted	Beds	Basal nets	Average Patients	Births
Alaska	10	2,917	388	50	170	195
Canal Zone	10	21,741	2,117	38	1,478	912
Hawaii	43	39,178	4,666	172	3,062	1,610
Philippine Islands	92	42,985	8,425	352	3,915	5,665
Porto Rico	39	11,411	2,605	100	1,885	514
Virgin Islands	2	813	114	12	55	87
Totals (1927)	204	119,523	18,255	729	12,872	8,416
(1931)	202	104,541	17,401	651	12,435	7,345

tals over last year but indicate increased capacity and increased patient population. The hospitals of Canal Zone admitted 21,741 patients as against 16,605 last year. The hospitals of Hawaii increased from 42 to 45

and admitted 39,178, as against 24,693 last year. The number of births recorded there was 1,610, as compared with 1,090 last year. The Philippine Islands and Porto Rico each show slight increases in the number of patients admitted and the number of births.

METHODS OF REGISTERING AND APPROVING HOSPITALS

The inclusion of any hospital in the Register is an indication that evidence concerning irregular or unsafe practices in that hospital has not been available to the

Hospitals, Sanatoriums and Related Institutions

	Hospitals	Beds	Basal nets	Patients Admitted	Average Census	Births
Hospitals and sanatoriums	5,065	840,704	49,816	6,875,095	664,810	699,777

Total registered hospitals	6,562	1,014,354	52,232	7,228,151	808,445	710,884

Council On Medical Education and Hospitals. Considerable investigation is carried out in the case of each hospital before it is admitted to the Register.

First, hospitals supply information regarding their capacity, equipment, classification and list of staff. Each member of the staff is then looked up in the biographic files of the Association. Information and advice are obtained from the secretaries and other members of the county medical societies, from state, city or county health departments, from the councilors of the state medical associations for the district in which the hospital is located, and from other sources. Investigation of hospitals for internship and residency approval is more thorough and comprehensive than for registration alone.

A personal visit by a member of our staff of hospital examiners is made to each hospital approved, or applying for approval, for internships or for residencies. An increasing number of other hospitals are being inspected.

HOSPITALS REFUSED REGISTRATION

There are 527 institutions which, because of alleged unethical or questionable practices, admission to their staffs of members who are seriously unqualified, either

morally or professionally, flagrant methods of advertising or for other valid reasons are deemed unworthy of being included in any published list of reputable hospitals. The 527 unregistered institutions have only 15,791 beds or a little over 1 per cent of all hospital beds. The distinction of having the largest number of unregistered hospitals belongs to California, where there are 77 such institutions.

DEVELOPMENTS IN EDUCATIONAL ACTIVITIES OF HOSPITALS

As in almost all other phases of institutional activity, evidence is presenting itself that the educational functions of hospitals require some readjustment. Little concern need be felt that interns and residents will ever be less essential to hospitals. The house staff system, representing as it does a remarkably effective organization at very reasonable terms and, above all, quite genuinely satisfactory to every one concerned, will not be gravely affected by altered financial circumstances.

Nevertheless, changing trends are manifest. The economic situation is one factor. Likewise, and somewhat as a corollary, opinions of medical educators on hospital training (in fact, on medical education as a whole) have undergone revision.

ECONOMIC FACTORS

Hospitals in the last two years have witnessed a decided change in the attitude of members of the house staff. Since private practice, under existing circumstances, is relatively unattractive to these younger men, owing to uncertain financial returns and to strong established competition, longer periods of internship and residencies make a more favorable appeal. Despite precarious circumstances even for well established institutions, the hospital stands as a haven of security from which recent graduates increasingly hesitate to separate themselves.

The effect of this process has been to decrease the gap that has recently existed between the number of internships offered and the number of candidates presenting themselves. For the first time in a number of years, not too many house positions are available.

The hospital, in the past, has competed strongly for desirable interns. In fact, this competition has been the principal incentive for observing and maintaining adequate standards of training. With lessening competition for interns, it is reasonable to suppose that a lowering of standards would occur were it not for the supervision exercised by the Council.

Such an eventuality seems unlikely. Efforts that have been expended in attracting interns represent an investment not lightly to be relinquished. Furthermore, the habit of thinking along educational lines has been beneficial. The presence of interns is not only helpful but stimulating.

The trends apparent at the present time are increased duration of service for many interns, a consequent reduction of the number of available openings, a modest drop in salary scales, and a tendency, because of the desirability of house positions, to approach more closely to what has been characterized as "practical discipline." It has occurred to not a few educators that some danger lies in extensive periods of hospital service, that a tendency to overdependence on hospital facilities is induced and that such practitioners are hampered in handling even ordinary illnesses such as are commonly encountered in general practice.

CHANGES IN POINT OF VIEW OF MEDICAL EDUCATORS

Just such considerations are presented in the recently published Report of the Commission on Medical Education, which contains a chapter on the internship. Elsewhere in that report, evidence is adduced indicating the necessity for reevaluating the demands made on

practitioners and altering medical education (including the internship) to meet these demands. The average intern spends too much time in acquiring a superficial acquaintance with technical surgical procedures, a process that often prompts him in his early professional career to attempt operations which he is not qualified to do. Other refinements in special practice take up time that could more profitably be spent in mastering the diseases which he will encounter during his first years of practice. His training should rather equip him to care with greater adequacy for such conditions as minor surgery and fractures, general medical diseases, pediatrics and infant feeding, and obstetrics.

The internship, then, in the opinion of these educators, needs realignment on the basis of these more practical concepts. The importance of experience in the outpatient department is emphasized as reproducing more closely the conditions of actual practice. Likewise, community medical needs should be taught the young physician, to prepare him for accepting a leading rôle in the development of preventive medicine and public health.

A swelling tide of criticism has been directed against short surgical services consisting mainly of experience in the operating room, represented by the one year

Allowances for Interns in Approved Hospitals, 1923-1932

	Number of Hospitals				Number of Interns

Totals	510	578	664	696	3,110	4,062	6,124	6,261

"straight" surgical services, and in a more aggravated form in many of the "rotating" services, where the intern is assigned to surgery for a period of three or four months. The *theory* of the rotating internship is that it provides an all round training for general practice. In *practice*, too often it inspires the intern with an entirely unwarranted self-confidence and sends him out into the world a surgeon whose skill is acquired, if ever, at great cost to the public. Preparation for general practice can never be too thorough or too complete. By all means it should include surgical diagnosis, the handling of emergencies, minor surgery, and fractures. But in many of the smaller hospitals, existing on the income from private patients, these phases of surgery are reduced to a minimum, while the bulk of the work consists of major elective operations. It may be, then, that surgery will come to be regarded as a specialty and that operating room experience will be confined, as far as may be practicable, to residencies of not less than two years' duration.

In the arrangement of services, greater flexibility is desirable in anticipation of the various phases of medical practice. The requirements of men who will enter specialties must be provided for as well as the needs of those who contemplate general practice. The problems of communities in which one is to practice must be considered and the requisite training in various departments of medicine should be provided for during the internship.

Reference to the table, which presents the latest available figures, will furnish indisputable proof that compensation in itself is still an unimportant consideration in the choice of internships. It will be noticed that although a greater number of hospitals must pay their interns in order to attract applicants, even so, fewer interns are paid. An increasing number of approved hospitals using more interns per hospital usually offers such valuable teaching opportunities as to make the receipt of a cash allowance a minor consideration.

All these changes point to a more complete reliance on the staff as a definite guiding force than heretofore. The increasing duties of the intern committee and introduction of new staff activities described from time to time in *THE JOURNAL* will, of necessity, induce greater rather than less supervision of all house staffs.

No implication of lower standards arises—rather a maintenance of present educational levels with movements away from overstandardization and toward more flexibility. Such a redefinition of motives is contemplated for internships. A start in this direction has already been made for residencies.

THE REVISED REQUIREMENTS FOR RESIDENCY HOSPITALS

The recent intensification of interest in the certification of specialists has led the Council to inaugurate several new principles in its approval of residencies. It does not consider a hospital residency as sufficient in itself to qualify a physician as a specialist. As an introduction, however, to well established postgraduate courses a residency is deserving of credit. Many hospitals, both general and special, have splendid facilities for this type of training.

All are familiar with the biographic cards maintained for each physician in the United States at the office of the American Medical Association. From this source, the American Medical Directory draws its principal information. During the past year on receipt of information from all hospitals in the country, credit for residencies on an educational basis has been incorporated in these biographic records.

All approved residencies are given full credit without further investigation. In general hospitals not approved for residencies, additional years of service are classed as additional internships, or if in special hospitals as periods of institutional experience of greater or shorter length.

Elsewhere in this issue will be found the recently revised "Essentials in a Hospital Approved for Resi-

dencies in Specialties." A careful reading will elicit the intention of elevating the term "residency," of restricting its use to services of definitely educational value, and of regarding the residency as one of the preliminaries to special practice.

If active staff cooperation is essential during the internship, it is equally so during the residency. Responsibility for residency training, however, has been placed in the hands of individuals or small committees for more effective control. No residency will be approved which does not provide for supervision by responsible proficient practitioners of the specialty.

The duties and privileges of residents have also been outlined. Likewise the importance of the laboratories and their directors, of the library, and of the records has been stressed. Necropsies, still a useful index of the scientific mindedness of hospital staffs are urged, and with increasing stress on the care with which they are performed.

Discriminating judgment must be exercised in those hospitals using both interns and residents that proper balance be preserved—that one group be not favored at the expense of the other. It is generally conceded that residencies make for better internships, for not only is there better supervision but the prospect of attaining the position of resident stimulates greater effort among the interns. Some educators believe that ultimately internship and residency hospitals will be completely separated. No such action need be envisaged if the staff recognizes the aims and requirements of both groups.

The attention of special hospitals (particularly tuberculosis and psychiatric) is called to the proviso which states that the first three years of residence in such institutions will be considered as educational and approval can be obtained on that basis. Other requirements, as stated in the Essentials, of course, must be met. This treatment is necessary in order to differentiate clearly between those individuals still in training and those who have attained reasonable proficiency in the specialty such as three years of residence implies. Subsequent years of service are classed as institutional experience only.

These considerations reemphasize the fact that internships and residencies are not static, that, though their value has been incontrovertibly established, they are still amenable to improvement. House appointments of the future show promise of being more efficiently conducted, more definitely aligned with the practical needs of physicians.

ESSENTIALS IN A HOSPITAL APPROVED FOR RESIDENCIES IN SPECIALTIES

Prepared by the Council on Medical Education and Hospitals of the American Medical Association

The training of residents in special branches of medicine or surgery represents advanced or postgraduate instruction for physicians whose ultimate aim is to prepare for the practice of a specialty. These residencies, therefore may be regarded as recognized work toward specialization but not as sufficient preparation in themselves to qualify a physician as a specialist. For rating as a specialist, a physician should continue his studies in a recognized postgraduate school or department of a medical college. A list of qualified postgraduate institutions in the United States and elsewhere is available on request.

The term *residency* shall be restricted to definite periods of not less than twelve months training, subsequent to internship.

I Applicants for Residencies

Candidates for residencies should be selected from graduates of approved medical schools, who have served an internship in an approved hospital or who have had two or more years in practice.

II Credit for Residency Training

As the postgraduate work of each physician is recorded in the biographic files maintained by the American Medical Association it is incumbent that all hospitals approved for residencies in specialties make annual reports to this office.

Periods of service in hospitals approved by the Council for residencies in specialties are given full credit without further inquiry. Periods of service in unapproved hospitals are recorded as additional internships in general hospitals and as institutional experience in special hospitals.

Clinical Fellowships are distinguished from residencies as being extended periods of graduate study, under university control, which are provided for by endowment or other financial arrangement. They usually, though not always, involve the performance of original investigative work and frequently the fulfilment of definite requirements for advanced degrees.

Residencies are offered by hospitals in medicine, surgery and their subdivisions.

III Eligibility

REGISTRATION—Previous admission to the Hospital Register of the American Medical Association is essential.

SIZE—The size of the hospital is not a primary consideration. The clinical material, however, should be sufficient to enable the resident to observe the principal manifestations of the disease, or diseases, he is studying.

PLANT AND EQUIPMENT—The hospital buildings should be such as to assure the safety and comfort of the patients. There should be such equipment, appliances and apparatus as are commonly employed in the specialty in which training is offered and in the use of which the resident should become proficient.

IV Staff

There must be an organized staff of ethical, licensed physicians holding the degree of doctor of medicine from acceptable medical schools. The particular specialties in which residents are being trained must be represented on the staff by well qualified, experienced and proficient physicians.

In general hospitals, the staff shall further provide a definite departmental organization in those branches of medicine in which residencies are offered. The chief of service in the department, either alone or as chairman of a residency committee in that department, shall assume direct responsibility for the training of the resident. He shall examine the qualifications of the candidates and form accurate conclusions as to the necessity for further training in the fundamentals. He shall supervise such research efforts as the residents conduct. He shall stimulate others of his staff to give instruction and sympathetic cooperation which graduate students require during their hospital service.

It is expected that there shall be at least monthly clinical-pathologic conferences or other regular staff meetings at which histories and clinical observations in selected cases may be reviewed, particularly when the death of patients has necessitated special study including necropsy performance. In addition to meetings of the staff as a whole, it is desirable that departmental conferences be conducted in which the resident may take an active or even the principal part to the end that the character of the service given by that department to its patients may be recurrently evaluated.

V Laboratories

PATHOLOGIC SERVICE—There must be a clinical laboratory equipped to perform routine and special tests in charge of a qualified pathologist. He shall be prepared to cooperate fully in the training of the residents and to supervise any direct contact which the resident has with the laboratory.

Residents in pathology must serve under a pathologist who is at least eligible for the Council's approved list of specialists in pathology. In addition, the department should provide apparatus, reagents or materials necessary to the operation of a modern pathologic laboratory.

RADIOLOGIC SERVICE—The roentgen-ray laboratory shall be under the direction of a qualified roentgenologist, proficient in the mechanical and interpretative functions of his specialty. He must likewise cooperate in all matters pertaining to the residencies which fall within the purview of his department. The department should contain roentgenologic, roentgenoscopic and, where required, therapeutic equipment.

Residents in roentgenology or radiology should serve under a specialist who at least is eligible for inclusion in the list of qualified roentgenologists as prepared by the Council. The laboratory should contain complete diagnostic and therapeutic equipment.

VI Necropsies

Thoroughness in postmortem performance should be emphasized. All hospitals desiring approval for the training of residents must examine post mortem 15 per cent or more of their fatal cases. The necropsy records should be complete, should be kept on file, and should include a summary of the clinical record.

Necropsies should be witnessed as often as possible by the resident. He may, with value, participate in their performance, in the writing of the protocols, and in preparing the final record in which appears a detailed description of both the gross and the microscopic observations.

VII Medical Library

The hospital shall maintain, or provide ready access to, an adequate medical library.

VIII Histories and Records

There must be complete histories, giving the patient's complaint, physical examination at time of admission to the hospital, preliminary diagnosis, laboratory observations, descriptions of operation, if any, daily record of case, final diagnosis, condition and date when discharged from hospital, end-results, and, in case of death, necropsy observations, if necropsy is performed.

The histories should show by signatures, or initials, all persons writing them or parts of them as well as the staff members by whom the histories are verified. Likewise, all orders and progress notes should be initialed or signed.

The records should be in charge of some competent person, preferably a trained record librarian. Alphabetical and diagnostic indexes of the patients should be maintained and the records filed so as to be readily accessible from either index.

IX Work of the Resident

The resident's term of service should cover at least twelve months.

Aside from daily contact with patients and staff men, the assumption of responsibility is the most valuable aspect of a residency. As ability is demonstrated, an increasing amount of reliance should be placed in the judgment of a resident both in diagnosis and in treatment. The essential strict supervision, however, should never be relaxed.

The resident should be encouraged to contribute to the effectiveness of hospital service by some investigative work. This may take the form of research in the hospital laboratories or wards, summaries of literature, or the preparation of statistical summaries and analyses derived from the hospital record department.

X Resident-Intern Relationship

Those hospitals training both residents and interns should recognize their responsibility to both groups and not curtail too sharply the opportunities ordinarily given to interns by an excess of solicitude for the residents. The residents may, with profit, teach the interns, supervise their record work, and direct the treatments which interns administer. They should not, however, act so as to diminish the contact of the interns with the attending men nor assume the supervisory or disciplinary functions of the staff intern committee.

XI Residencies in Special Hospitals

For educational purposes the Council will recognize not more than the first three years of service in a special hospital, notably those for psychiatric and tuberculous patients.

XII Admission to the Approved List

Approval is granted hospitals only by application, and subsequent to investigation by the Council staff. Withdrawal of approval occurs when serious lack of conformity to the Essentials is revealed or if vacancies continue longer than two years.

Hospitals that wish to be approved for the training of residents should apply to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago.

List of Hospitals and Other Institutions Caring for Patients with Nervous or Mental Diseases The Complete List of Registered Hospitals will be Found on Pages 911 to 972

HOSPITALS REGISTERED BY THE AMERICAN MEDICAL ASSOCIATION

The following list contains the names of 6,562 hospitals, sanatoriums and related institutions that are located in the United States and 204 in the insular possessions. It omits the names of 527 hospitals which, after investigation, were not accepted. The inclusion of the name of any institution may be taken as an indication that evidence concerning irregular or unsafe practices in that institution has not come to the attention of the Council on Medical Education and Hospitals. The list in each state is given in two sections: (1) hospitals and sanatoriums, and (2) related institutions. The related institutions include some general hospitals lacking certain essentials, nursing homes, school infirmaries, prison infirmaries, custodial and other institutions designed to give some medical, nursing or convalescent care in an ethical and acceptable manner, but not strictly hospitals. In the statistics the two classifications are consolidated. A special list of hospitals for nervous and mental patients is presented separately in this issue.

KEY TO SYMBOLS AND ABBREVIATIONS

- * Approved for general internship, the fifth year in medicine, by the Council on Medical Education and Hospitals
- + Approved for residency in a specialty for graduates in medicine who have already had a general internship or its equivalent in practice
- o School of nursing accredited by state board of nurse examiners

- o Affiliated for nurse training on state accredited basis
- o Outpatient department
- D Dental service

The column headed "Type of Service" tells what diseases or conditions are treated in each institution, as follows:

Chil	Children's	Epl	Epileptic	Iso	Isolation	N&M	Nervous and mental
Conv	Convalescence and Rest	FFNT	Eye, Ear, Nose and Throat	Inst	Institutional	Ortho	Orthopedic
Chron	Chronic	Gen	General	Mater	Maternity	Sk & Ca	Skin and Cancer
Dr & Al	Drug and Alcohol	Indus	Industrial	MenDef	Mentally Deficient	TB	Tuberculosis

The column headed "Control" indicates for each institution the ownership, control, or auspices under which it is conducted, as follows:

Cy & Co	City and County	Indian	U S Indian Service	Part	Partnership
Fed	Federal	Indiv	Individually owned	USPHS	United States Public Health Service
Frat	Fraternal	Indus	Industrial	VetAd	Veterans Administration
Indep	Independent hospital association

HOSPITAL INSURANCE AND MEDICAL CARE

In times of sickness and misfortune, charlatans flourish. The desperate man grasps at any straw and is ready to try any scheme that offers something for nothing or more for less than it costs. As is revealed by the report of the Council on Medical Education and Hospitals elsewhere in this issue, there are in this country 6,562 hospitals with more than a million beds. More than 200,000 of these beds are not occupied. This is no doubt largely a reflection of the current economic situation. It is unquestionably associated with the fact that the government hospitalized gratis large numbers of veterans who suffer from non-service connected disabilities and who were well able to pay for hospital care. The failure of occupancy of these beds represents a serious situation to the hospitals. Fortunately, an order has already gone forth ordering admission for the present at least of emergency cases only. Moreover, the current economic situation has thrown into medical service a considerable number of business men who see in various insurance and other commercial medical schemes an opportunity for recouping fortunes lost through other business ventures. They are perhaps stimulated to entrance into the medical field by the unusual attention focused on this problem by the publicity given to the reports of various committees and commissions during recent years. It is unfortunate that lay and medical organizations in many cities were urged by the publicity director of the Committee on the Costs of Medical Care to embark on half-baked experiments in changing the nature of medical practice.

In many communities, hospital insurance schemes have been developed which are offered as exceptional opportunities to great numbers of people to protect themselves against unanticipated hospital bills. The Bureau of Medical Economics of the American Medical Association has analyzed many such schemes, and reprints are available of these analyses as they have appeared in *The Journal*. The Council on Community Relations and Administrative Practice of the American

Hospital Association has recently analyzed various periodic payment plans for the purchase of hospital care, sometimes called group hospitalization, and has apparently given its approval to such plans, subject, however, to certain restrictions.

The medical profession hesitates to approve any such plan because these plans fail to provide for complete participation of most if not all the recognized hospitals in the community, complete participation of the reputable physicians of the community and, associated with this, free choice of physician by the patient and free choice of hospital under the policy. The most important ingredient in medical care is the personal attention of a competent physician. The committee of the hospital association recognizes the necessity for having patients admitted on the recommendation of their own physicians and cared for by their own physicians. They feel that such plans should not disturb any arrangement for the payment of fees between physician and patient or in any way disturb the preexisting normal relationship between the doctor and those he serves. Emphasis is placed on the fact that it is the hospital bill which forms the chief difficulty for patients in the current financial situation.

THE JOURNAL has repeatedly emphasized the danger of exploitation of such plans by commercial interest which charge excessively for selling the service or promoting it and which frequently have insufficient financial backing to carry responsibility. The patient and the physician who may be involved in such scheme should realize that the clauses in fine print which limit the number of conditions covered by the policy, which limit the term of stay of the patient in the hospital and which otherwise tend to invalidate the policy demand most careful consideration. The committee of the hospital association recommends that the direction of activities in all such schemes should remain in the hands of a nonprofit organization representing the hospitals and should never be transferred to an business agency. One of the chief menaces to medicine under such plans is the incitement to solicitation for patients and competitive underbidding.

Today all such plans are in an experimental stage. Their consideration demands the most careful attention of the most astute minds available in both the medical and the hospital fields. These schemes are fraught with danger in placing hospitals on a competitive basis for patients, offering service at prices lower than warranted with subsequent skimping of the service, and, most serious of all, disruption of medical organization and of the whole institution of medicine. That institution has an enviable record of thousands of years of service to the public. Economic depressions have come and gone many times in the history of the world. The present predicament should not be permitted to destroy or disrupt institutions that have stood the test of time.

"GINGER POISON"

One of the most pathetic by-products of the governmental effort to enforce prohibition in this country involved the adulteration of jamaica ginger, which has come to be purchased widely and consumed because of its liberal content of the proscribed ethyl alcohol Tincture of ginger U S P has an alcoholic content of about 76 per cent. A manufacturer, seeking a cheap adulterant for the product, came on a little known substance, triorthocresyl phosphate which he incorporated freely into his alleged jamaica ginger. The illicit use of this product as a beverage was followed by a wave of so-called jake paralysis in many sections of the United States early in 1930. The adulterated concoction sold in drug stores in many states, is reported to have caused deformity and paralysis in from fifteen to twenty thousand victims, many of whom have died.

Great credit is due to the U S Public Health Service for having discovered the real cause of a most baffling series of symptoms of "jake paralysis".¹ A peculiarity of the intoxication is its insidious onset. The prominent manifestations, notably the paralytic consequences, usually fail to become manifest for some time. Then there appears a symptom complex characterized by bilateral and symmetrical flaccid paralysis for the most part of the distal muscles of the lower and to a lesser extent of the upper extremities, with practically no sensory disturbances. The results were not such as pharmacologists might be led to expect from soluble phenols and cresols. Consequently the government experts have engaged in an elaborate study of compounds in which phenolic groups are firmly bound in combination with phosphoric acid. Recently it has been pointed out² that an apparently new type of relationship between physiologic action and chemical constitution thus presented itself. This is a matter of practical as well as theoretical concern, for some of the phenolic compounds used in therapeutics such as phenyl salicylate and guaiacol carbonate, belong to the same general class as the objectionable orthocresyl phosphoric ester.

The investigations disclose that by altering the chemical constitution of the phenolic esters in certain directions it is possible to produce compounds of widely different pharmacologic action, their effects in the animal body varying all the way from the purely phenol-like action to the singular specific type of neurotoxic action marked by a long latent interval or "incubation period". According to the government

investigators,³ the essential requirements that would endow a phenol ester with neurotoxic properties would seem to be (1) lipid solubility, (2) a moderate degree of stability, (3) an anion not easily oxidizable, and (4) a course of distribution in the body so that the phenolic disintegration product of hydrolysis may escape the detoxifying process of oxidation, conjugation and elimination. Such properties, as in the case of the "ginger poison," tend to explain why the action is so insidious and why the effects usually develop only after a latent interval of many days. In its action it bears little or no resemblance to the phenols. It has a selective action more or less limited to certain well defined physiologic units of the nervous system, which endows them with specific neurotoxic properties. The only possible good arising from this incident is the lesson it has taught concerning some unexpected and insidious reactions to which the organism may be exposed.

**ROENTGENOGRAPHICALLY NEGATIVE
PULPLESS TEETH AS FOCI
OF INFECTION**

In searching for foci of infection as a cause of systemic disease, the teeth are most often suspected. Satisfactory roentgenograms, together with careful direct inspection and tests for vitality, make an evaluation of the teeth as sources of infection less difficult than is the case with the other common foci. However, there is a surprising lack of agreement as to which teeth are to be considered foci of infection. Often the condition is obvious, but difficulty arises in deciding the fate of (1) pulpless teeth showing roentgenographically extremely little or no change at the root, (2) root fragments left from previous attempts at extraction which are roentgenographically negative, (3) so-called residual areas of bone condensation or rarefaction at the site from which a tooth has been removed, and (4) teeth that respond to the electric current and have only slight changes at the tip and about the shafts in films. That pulpless roentgenographically negative teeth constitute a major medical and dental problem is shown by statistics of various workers covering the roentgenographic examination of many hundreds of teeth. These statistics reveal that from 80 to 90 per cent of the mouths of adults contain teeth with filled root canals and that an average of 69.5 per cent of these pulpless teeth show roentgenographic evidence of periapical infection. They also seem to indicate that a high percentage of pulpless teeth eventually show roentgenographic evidence of bone change at the apex, even though there is no evidence of bone destruction at the time the root canals are filled.

Lillie, R. D. and Smith, M. I. The Histopathology of Some Neurotoxic Phenol Esters *ibid.*, p. 54.

From an experimental point of view, Haden¹ considered the total bacterial count of the area at the roots of the teeth the best index of their disease-producing potentialities. He made quantitative cultures in deep tubes of dextrose-bram-agar of 600 pulpless teeth which he considered roentgenographically negative. By his technic, 46.2 per cent of such teeth were found to have ten or more colonies to the tube. Cultures of 400 vital teeth that were negative roentgenographically were taken in the same way as controls. This group had ten or more colonies to the tube in only 4.8 per cent. The percentage above this figure in a series of 500 pulpless teeth with positive roentgenographic evidence of bone destruction was 62.8. Streptococci were the predominating organisms in all cultures. He considers pulpless roentgenographically negative teeth almost as potent in causing systemic disease as those having frank destruction at the roots.

Many instances of prompt improvement in systemic disease following removal of pulpless roentgenographically negative teeth were cited, as well as an extensive series of animal inoculations in which typical lesions, such as arthritis and endocarditis, were produced with the organisms recovered from these teeth.

Recently, Rhoads and Dick² made a study to throw additional light on the pathologic significance of pulpless roentgenographically negative teeth. Quantitative cultures were made from the apices of twenty-nine roentgenographically negative pulpless teeth, and cultures of a series of fourteen vital healthy roentgenographically negative teeth taken in precisely the same manner were used as controls. In their series, in order to be considered roentgenographically negative, the film of the tooth of which a culture was taken had to reveal no absorption along the shaft of the tooth and no rarefaction or condensation in the bone surrounding the apex. Only teeth having root canal fillings visible in the roentgenogram were used in the pulpless tooth series.

Careful technic was used in order to avoid contamination in extracting the teeth. The average bacterial count of the twenty-nine pulpless roentgenographically negative teeth was 759,574, while the average count of the controls was 1,876. While Rhoads and Dick state that some of the "control" teeth may have had bacteria growing at their roots, they think the growth obtained represented unavoidable contamination. However, the difference in the counts in the two series is too great to be credited to chance contamination.

Cultures of the pulpless teeth yielded green forming streptococci in every instance. In all but two they were the predominating organisms. The other organisms frequently found were *Staphylococcus albus*, gram-negative bacilli and hemolytic streptococci.

Rhoads and Dick did not draw conclusions from the clinical results obtained in their patients because in but few instances was the single extraction the only measure taken to relieve the symptoms of systemic disease. However, it is significant that practically all their patients experienced some improvement, and in some instances the assumption seemed justified that extraction of the teeth with filled root canals was responsible for the clinical result obtained.

In view of the results of quantitative cultures by Haden and by Rhoads and Dick, it seems justifiable to regard all pulpless teeth as possible foci of infection whether they show apical changes in the roentgenograms or not. At least this position should be taken in the presence of systemic disease of a type usually associated with focal infection.

Current Comment

SURGICAL SHOCK

One of the pathologic conditions with which the surgeon is constantly confronted is shock. This syndrome was particularly prominent in military hospitals during the World War, and in more recent years the increase in accidental injuries in civil life has raised again the question of the etiology of surgical shock. The older view considered the condition essentially a toxemia, the products of tissue injury, either primary or after a period of autolysis or other decomposition, entered the circulation and, acting as capillary poisons, produced extreme vasodilatation and permitted the loss of more or less fluid through increased permeability. The paradoxical statement that a shocked individual suffered from hemorrhage into the vast splanchnic capillary bed arose during the war from these considerations. Within the last three years, editorial comment in *THE JOURNAL* has at various times called attention to experimental studies from which the general conclusion was drawn that the shock following traumatic injury and burns can be explained largely on the basis of actual loss of fluid from the circulation into the interstitial spaces of the injured tissues. Fluid equivalent to surprisingly large proportions of the total blood volume has thus been shown to accumulate in the injured tissues. Only infrequently does this "edema" fluid contain red blood corpuscles, usually its composition approaches that of plasma. The latter view of the etiology of shock has the weight of cogent recent experimental evidence in its favor, yet a closer scrutiny of the details of both apparently conflicting theories reveals some strikingly similar points. The toxic theory assumes a passage of fluid out of the capillary walls to some extent, as well as a vasodilatation. The more recent view postulates an initial injury to the capillaries, to some extent an actual rupture of the vessels permitting loss of whole blood but largely an increase in permeability to plasma proteins; the latter condition must be brought about by a local factor resulting from the injury, whether or

¹ Haden, K. L. *Dental Infection and Systemic Disease*. Philadelphia: Lea & Febiger, 1928.

² Rhoads, J. S., and Dick, C. F. Roentgenographically Negative Pulpless Teeth as Foci of Infection: Results of Quantitative Studies. *J. A. Dent. A.* 19: 1884, 1928.

not this factor is called a toxin. Further than this, however, the two theories lay emphasis on divergent circumstances in the primary causation of shock. Whatever the final answer to the question of the detailed description of the etiology of shock proves to be, the investigators in this field have again called attention to the vital importance of the integrity of the volume of the blood apart from its composition.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9 15 to 9 30 a m (central standard time) over Station WBBM (770 kilocycles, or 389.4 meters). The subjects for the week are as follows:

March 28 Dependable Clinical Thermometers
March 30 The Voice

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9 45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

April 1 Baby Learns to Walk

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

COLORADO

University News—The eighth annual series of clinics of the University of Colorado School of Medicine and Hospitals was held, March 22-24. The general outline of the program included obstetrics and gynecology, orthopedics and dermatology, in the morning, and neurology and tuberculosis in the afternoon of March 22. Clinics on medicine, urology and proctology were carried on in the morning, March 23, while the afternoon was devoted to ophthalmology, pathology and psychiatry. The forenoon, March 24, was given over to general surgery and pediatrics, and the afternoon to otolaryngology and radiology.

Publisher Leaves Fortune to Foundation—Through the will of Mr. Frederick G. Bonfils, late publisher of the *Denver Post*, the bulk of his estate, after provision for members of his family, will be devoted to charitable, educational and scientific purposes. The funds will be distributed through the Bonfils Foundation, which he created, Dec. 17, 1927, as "a corporation, not for profit, organized for charitable, benevolent, scientific medical and public educational purposes" (*THE JOURNAL*, Feb. 25, 1928, p. 622). Trustees are to have discretion in the use to which funds of the foundation are to be devoted in promoting "the general well-being of mankind," the *New York Times* reported. Estimates have placed the estate at \$10,000,000 and upward, it was stated.

DELAWARE

Bill Introduced—Senate Substitute for S. 133, to amend the workmen's compensation act, proposes to compensate employees who contract in the course of their employments any one of certain named occupational diseases.

DISTRICT OF COLUMBIA

District Bills in Congress—S. 450, introduced by Senator Capper, Kansas, proposes to empower the health officer of the District to authorize the disinterment and reinterment of bodies in cases in which death has been caused by contagious diseases. H. R. 1642, introduced by Representative McLeod, Michigan, proposes to authorize an appropriation of \$50,000

for the alteration and repair of Eastern Dispensary and Casualty Hospital in the District of Columbia.

University News—Dr. Stanhope Bayne-Jones, New Haven, Conn., gave one of the lectures in the Smith-Reed-Russell Society series at George Washington University, February 23, on "Bacterial Toxins." Maurice C. Hall, D.V.M., chief, zoological division, U. S. Bureau of Animal Industry, spoke, March 16, on "Drama Anthelmintica," and Dr. George B. Jenkins gave the February faculty seminar on "Comparative Embryology of the Central Nervous System."

Society News—Dr. Joseph L. Gilbert addressed the George M. Kober Medical Society in Washington, March 20, on "Traumatic Psychoses." The society was addressed February 20, by Charles L. Smith, D.D.S., on "When Should a Tooth Be Extracted?"—The Medical Society of the District of Columbia heard Dr. James G. Cumming speak, March 1, on "The Bonus Army: Health and Sanitary Problems," and Drs. John deJ. Pemberton, Rochester, Minn., and George E. Pfahler, Philadelphia, March 8, on "Results of Surgical Treatment of Hyperthyroidism" and "Radiation Treatment of Hyperthyroidism."

GEORGIA

Bill Enacted—S. 135, amending the pharmacy practice act by requiring all applicants for registration as pharmacists to be graduates of schools of pharmacy recognized by the board of pharmacy and, in addition, to have twelve months of practical experience in places where prescriptions of physicians are dispensed by licensed pharmacists, has become a law.

ILLINOIS

Low Birth and Death Rates—Complete provisional statistics for 1932 give Illinois the lowest birth and death rates of record in the state, according to the state health department. There were 83,183 deaths and 111,523 births reported, giving rates per thousand estimated population of 107 and 144, respectively. The number of births in 1932 was 7,265 short of the 1931 figure and 29,914 below the 1924 record, the year of highest birth registration. New low death rates were recorded for measles with a rate of 0.7 per hundred thousand, diphtheria, 3.1, tuberculosis, 5.5, infant mortality, with a rate of 5.2 per thousand live births reported. Increases were noted in the death rates for heart disease, with 23.5 deaths per hundred thousand of population against a previous high of 22.1, cancer, 11.6 against 11.2, and diabetes, 2.67 against 2.57. Automobile accidents resulted in 2,104 deaths, giving a rate of 27.1 per hundred thousand as compared with 2,333 deaths and a rate of 28.7 in 1931.

Chicago

Personal—Dr. Andrew J. Toman has been appointed director of the House of Correction and Police Emergency Hospital, succeeding Dr. Frank J. Jirka, who is now state health officer. —A meeting in memory of the late Dr. Emil G. Beck was held, February 12, at the John B. Murphy Hall, speakers were Drs. Frederic A. Besley, Waukegan, Victor L. Schrage, Carl A. Hedblom, James T. Case, Benjamin H. Orndoff and Mr. Horace J. Bridges.

Giant X-Ray Tube—A transformer delivering 1,200,000 volts and a giant x-ray tube with a capacity of from 800 to 1,000 kilovolts are being installed at Mercy Hospital. The special building contains three floors, the first of which houses a 300 kilovolt transformer, and the second, a control room and a radium treatment room, and lead-enclosed cubicles. The treatment room for the high voltage roentgen rays is 10 feet long, 5 feet wide and 8 feet high. The tube will be activated by 10 to 30 milliamperes, so that the duration of treatment will be reduced to a fraction of the time formerly required. The radiation therapy department will be under the direction of Dr. Henry Schmitz.

INDIANA

Bill Enacted—S. 172, requiring instruction in the elementary public schools as to the effect of alcoholic drinks and narcotics on the human system, has become a law.

Course on Medical Economics and Ethics—The Indiana University School of Medicine is conducting a course in medical economics and medical ethics for the senior class. The purposes and content of the course have been approved by the Indiana State Medical Association, which has appointed a committee, composed of Drs. George J. Geisler, South Bend, Cyrus Clark, Jr., Indianapolis, and Garland D. Scott, Sullivan, to cooperate with the faculty of the medical school. The course opened, February 1, with a talk on "General Principles of Ethics" by Mr. Daniel S. Robinson, Bloomington. Among

subsequent speakers have been Drs J Maurice Barry, Indianapolis, on "Principles of Medical Ethics", Joseph H Weimstein, Terre Haute, "Work and Ideals of Organized Medicine", Dr Thurman B Rice, Indianapolis, "Duties of the Doctors in Safeguarding Public Health", Dr William N Wishard, Sr, Indianapolis, "Conduct of Consultations", Dr Willis D Gatch, Indianapolis, "Code of Medical Ethics", Dr James Oscar Ritchey, Indianapolis, "Prognosis," and Dr Cyrus J Clark, Jr, Indianapolis, "Problems of the Young Physician" Commg speakers and their subjects are as follows

Dr Olin West Secretary and General Manager, American Medical Association Chicago March 29 Newer Forms of Medical Practice
Mr Evans Woollen, Jr Indianapolis April 5 Saving and Safe Investment
Mr Charles Beckett Indianapolis April 12, The Mathematics of Life Insurance
Speaker to be announced April 19 Life Insurance Examinations
Dr Carl H McCaskey, Indianapolis, April 26 Office Equipment of the Doctor
Dr William R Davidson Evansville May 3 Work of the Indiana State Board of Medical Registration and Examination

Program of Reminiscences—The Indianapolis Medical Society, at its meeting, March 28, will hear a discussion of war experiences by members of the Lilly Base Hospital Unit. Each physician will relate his reminiscences from a special point of view as follows

Robert M Moore, internist
Eugene B Mumford, orthopedic surgeon
Raymond C Beeler and Ralph L Lochry, roentgenologists
Carleton B McCulloch commanding officer of a mobile hospital.
Joseph W Ricketts with a heavy artillery regiment.
Elmer Funkhouser ammunition train.
Frank C Walker surgical team at the front
Alois B Graham adjutant
Edmund D Clark commanding officer

Bishop Joseph M Francis will describe his experiences as a chaplain

IOWA

Bill Introduced—S 451 proposes to create a board of naprapathic examiners and to regulate the practice of naprapathy. "The practice of naprapathy shall be deemed to be the examination for, and charting of shrunken ligaments and connective tissues, and the scientific relaxing of such ligaments and connective tissues in accordance with Naprapathic Principles and Directopanning, but it shall not include operative surgery, osteopathy, nor chiropractic, nor the administration or prescribing of any drug or medicine now or hereafter included in materia medica." Naprapaths are to be entitled to all the rights and privileges granted to physicians and surgeons

KANSAS

Bills Enacted.—H 431 and S 340 have become laws. H 431 requires all licentiates under the medical practice act to renew their licenses annually and to pay annual fees of \$1 on or before October 1 but not earlier than July 1. The secretary of the board of medical registration and examination must strike from the register of licensed physicians the names of all physicians who have not paid their annual registration fees as required by law. Physicians whose names are so removed, however, may be reinstated by paying the secretary \$5 and submitting to him satisfactory proof of moral fitness. This new law strikes from the medical practice act the provision that no school of practice is to have a majority on the board of medical registration and examination and makes the secretary of the board the custodian of the common seal and of the books and records of the board. S 340 authorizes the governing body of any city operating under the commission form of government and having a population of more than 120,000 inhabitants to license and regulate all professions pursued within the limits of the city.

LOUISIANA

State Meeting Called Off—The Louisiana State Medical Society has dispensed with the annual meeting which was to have been held in Lake Charles April 25-27. A business meeting will be held at a date and place yet to be determined.

MAINE

Bill Passed—S 571 proposing to require all hospitals receiving any public funds to permit osteopaths to practice within their confines, has been passed by the senate.

Bills Introduced—H 1527 proposes to prohibit the dispensing or other distribution of vitamin or barbitol, except on the written prescription of a physician, dentist or veterinarian. H 1513 proposes to create a state board for the regulation of the practice of hairdressing and beauty culture. Licentiates are to be authorized among other things, to massage, cleanse, stimulate, manipulate, exercise or otherwise to improve or to beautify the scalp, face, neck, shoulders, arms, hands.

Society News—Dr Franklin A Ferguson spoke before the Portland Medical Club, February 7, on "The Physician and Leisure"—At a meeting of the Kennebec County Medical Association in Gardiner, February 16, Drs Forrest C Tyson, Augusta, and Theodore S Moise, Bangor, spoke on "Clinical Differentiation of Organic and Functional Mental Disorders" and "Surgical Treatment of Pulmonary Tuberculosis," respectively—Dr Frederick T Hill, Waterville, gave an illustrated lecture on "Bronchoscopic Diagnosis and Treatment of Various Conditions of the Respiratory Passage."

MASSACHUSETTS

Golden Wedding Anniversary—Dr Oscar Richardson and his wife, Dr Anna Gove Richardson, Lakeville, celebrated their golden wedding anniversary, Dec 20, 1932, at a reception given in their honor by friends. From 1892 until her retirement Mrs Richardson served on the staff of the Vincent Memorial Hospital, Boston, where, for several years, she was chief of staff. Dr Richardson was associate medical examiner for Suffolk County from 1913 to 1921. Since his retirement, he has published two books of poems.

Alumni Dinner—Dr Louis E Phaneuf, professor of gynecology, Tufts College Medical School, Boston, presided at the first annual alumni dinner of the school, February 27. The speaker of the evening was President John A. Cousens. Talks were also given by Drs Albert Warren Stearns, dean of the medical school, William Allen White, Roxbury, a member of the first class graduated from the school in 1894, Maurice Coleman Harris, New York, James W Manary, Boston, Edward L Merritt, Fall River, and Frank H Washburn, Holden.

Seventh Health Unit Dedicated—The seventh health unit established through the George Robert White Fund was dedicated, February 24, and presented to the city of Boston for the conservation of public health. Dr Shirley W Wynne, health commissioner of the city of New York, gave the dedicatory address. Gen Edward L Logan, manager of the fund, who presided, stated that \$3,000,000 had been spent for these units, which are maintained by the city health department. No more units are contemplated, it was said. The plan for the health units was conceived at a meeting in Boston about seventeen years ago with Drs Richard C Cabot, Francis X Mahoney and Charles F Wilkinsky, who is director of health in charge of the units (THE JOURNAL, Oct 11, 1930, p 1104). These units, the first of which was established in 1915 are educational institutions functioning for the training of the public in an understanding and practice of health conservation. Drs Mahoney and Wilkinsky also spoke at the dedication of the new unit.

MICHIGAN

Bills Introduced—H 318, to amend the laws relating to the commitment of the insane, proposes to require that a certificate of insanity be made by two physicians, one of whom must be the family physician of the person to be committed or, if there is no family physician, be a physician chosen in rotating order from a list of doctors of medicine in the county. H 319 to amend the laws relating to the medical treatment to be furnished by counties for the indigent sick, proposes to provide that all applicants for such relief be examined by their family physicians or, if there are no family physicians, by physicians chosen in rotating order from lists of licensed doctors of medicine in the several counties.

GENERAL

Northern Tri-State Medical Association—The sixtieth annual meeting of the Northern Tri-State Medical Association (Indiana, Ohio and Michigan) will be held in La Porte, Ind., April 11. A symposium on fractures will be presented by Drs. Paul B. Magnuson, Harry E. Mock and Raymond W. McNealy, Chicago. Among other speakers will be

Dr. Russell M. Wilder, Rochester, Minn., Diseases of the Parathyroid, with Special Reference to Parathyroid Overfunction

Dr. Arthur E. Hertzler, Kansas City, Early Clinical Diagnosis of Diseases of the Mammary Gland

Dr. Henry A. Christian, Boston, Other Uses of Digitalis Than in the Treatment of Cardiac Decompensation

Dr. Charles A. Elliott, Chicago, Management of Hepatic Disease.

Dr. Charles P. Emerson, Indianapolis, will speak at the annual banquet on "Neuropsychoses from the Internist's Point of View."

News of Epidemics—Two hundred and thirty-six cases of scarlet fever were reported to be under quarantine in Watertown, N. Y., March 11, and fifty-two cases in Herkimer, March 1.—Efforts were being made to vaccinate all school children in Kenosha, Wis., in February following an outbreak of smallpox in the schools. The Kenosha County Medical Society set aside special days on which they vaccinated children, giving the treatment free to indigent persons.—Three hundred cases of German measles were reported in Grand Rapids, Mich., March 11.—In New York City, an unusual number of measles cases have been reported, 1,867 new cases during the week ended March 15. Big Rapids, Mich., reported that 150 students of the town high school were ill with measles early in February, and in Buchanan, Mich., thirty-five families were said to be in quarantine, March 2.

Medical Provisions of the Economy Bill—The half billion dollar economy bill, which became a law, March 20, contains numerous features of significance to the medical profession. Under its provisions (1) medical and hospital care will be provided only for war veterans with disabilities directly traceable to war service, but domiciliary care will be available to those with permanent disabilities although such disabilities were not incurred in actual service, (2) payment for non-service-connected disabilities will be discontinued except in cases of permanent disability, and (3) retired officers, including medical officers, will have their pay reduced and benefits to emergency World War retired officers will be limited to those injured in line of duty prior to the armistice. The new law grants authority to the President to fix the dates of the beginning and end of hostilities for purposes of compensation, which will eliminate many from the rolls whose services were before or after the actual start and finish of the war. Pensions and allowances of veterans of all wars prior to the Spanish-American War are cut 10 per cent. An amendment prohibits removal from the pension rolls of any Spanish-American war veteran past 62 years old. The administrator of veterans' affairs is ordered to review immediately all claims allowed under the previous laws covering veterans' benefits in order to determine those entitled to receive benefits. The act also vests in the Chief Executive authority to cut the compensation of all government officers, civilian and noncivilian, up to a maximum of 15 per cent, the reduction to be based on a comparison of living costs of 1928 with those of the last six months of 1932.

Medical Bills in Congress—*Changes in Status* H R 2820, to maintain the credit of the United States government, has been passed by Congress. With certain exceptions, this act repeals all public laws granting medical and hospital treatment for veterans and authorizes the administrator of veterans' affairs, under such limitations as may be prescribed by the President, to furnish to veterans medical and hospital treatment for diseases or injuries. H R 1718, introduced by Representative Celler, New York, and relating to the prescribing of medicinal liquors, has been ordered favorably reported by the subcommittee of the House Committee on the Judiciary. This bill is sponsored by the American Medical Association. *Bills Introduced* H J Res 4 introduced by Representative Blanton, Texas, proposes to direct the President of the United States to use the army, navy and marine corps, the militia of the several states and the resources of the government in suppressing all smuggling into the United States of intoxicating liquors and narcotics. H J Res 59 introduced by Representative Bland, Virginia, proposes to grant

permission to Hugh S. Cumming, Surgeon General, John D. Long, medical director, and Clifford R. Eskey, surgeon, all in the Public Health Service, to accept and wear certain decorations bestowed on them by the governments of Ecuador, Chile and Cuba, for assistance rendered in matters relating to sanitation and health. H R 12, introduced by Representative Boland, Pennsylvania, proposes to erect a veterans' hospital in Lackawanna County, Pennsylvania. H R 14, introduced by Representative Cannon, Missouri, proposes to require the discoloration of poisons which resemble commonly used food-stuffs. H R 34, introduced by Representative Evans, Montana, proposes to increase the pensions of persons who have lost the sight of both eyes in line of duty in the military or naval service of the United States. H R 101 and H R 103, introduced by Representative Wolverton, New Jersey, proposes to make it mandatory that the administrator of veterans' affairs hospitalize any veteran who has served ninety days or more during any war "if in the opinion of the administrator an emergency exists requiring immediate hospitalization." H R 117, introduced by Representative Gibson, Vermont, proposes to regulate the importation of milk and cream, and milk and cream products, into the United States. H R 122, introduced by Representative Goss, Connecticut, proposes to regulate the use and sale of wood alcohol. H R 128, introduced by Representative Harlan, Ohio, proposes to provide additional compensation to veterans for the loss of use of an eye in active service in line of duty in the World War. H R 131, introduced by Representative Harlan, Ohio, proposes to provide that certain veterans not honorably discharged shall be admitted to veterans' administration homes. H R 144, introduced by Representative McKeown, Oklahoma, proposes to create, under certain conditions, conclusive service-origin presumptions for paralysis, paresis and blindness. H R 1499, introduced by Representative Englebright, California, proposes to authorize the erection of a veterans' hospital in the inland region of California. H R 1524, introduced by Representative Fulmer, South Carolina, proposes to provide for cooperation with the several states in the care, treatment, education, vocational guidance and placement, and physical rehabilitation of persons under the age of 21 years, who have physical defects such as affections of the joints, affections of the bones, disturbances of neuromuscular mechanism, congenital deformities, static and other acquired deformities that may be corrected or improved by orthopedic surgery or other surgical and medical care. H R 1527, introduced by Representative Griffin, New York, proposes to provide for medals of honor and awards to government employees for distinguished service in science or for voluntary risk of life and health beyond the ordinary risks of duty. H R 1535, introduced by Representative Kahn, California, proposes to authorize the erection of a veterans' hospital in California to be used for the housing, care and treatment of disabled women veterans only. H R 1551, introduced by Representative Ludlow, Indiana, proposes to erect a 150 bed addition to the veterans' hospital at Indianapolis. H R 1635, introduced by Representative Luce, Massachusetts, proposes to create a commission to study the hospitalization of war veterans. H R 1686, introduced by Representative Mitchell, Tennessee, proposes to erect a veterans' hospital in middle Tennessee. H R 1704, introduced by Representative Rudd, New York, proposes to grant hospital treatment in government-owned hospitals to postal employees suffering from tuberculosis, nervous diseases or kindred occupational ailments. H R 1741, introduced by Representative Carter, California, proposes to erect a 250 bed addition to the veterans' hospital at Livermore, Calif. H R 1759, introduced by Representative James, Michigan, proposes that for purposes of promotion, longevity pay and retirement there shall be credited to the officers of the medical administrative corps of the Medical Department of the Army all classified service rendered as clerks in the military establishment prior to July 3, 1916. H R 1766, introduced by Representative Gambrill, Maryland, proposes to provide medical services, after retirement on annuity, to employees of the United States disabled by injuries sustained in the performance of their duties.

CORRECTIONS

"Increased Suspension Stability of Erythrocytes"—In the article by Dr. Kamil Schulhof in THE JOURNAL, February 4, in the fifteenth line from the bottom of the first column on page 319 the number of minutes should read 120 instead of ninety. Ninety minutes applies to women.

Internships for Creighton Graduates—In table 14 in the Educational Number of THE JOURNAL (Aug. 27, 1932, p. 744) Creighton University School of Medicine is credited with 14 internships for the graduating class of 1931. This figure was incorrectly recorded and should be 53.

A National Eye Service

Until recently, patients of limited means requiring advice concerning eyesight and unable to pay the fees of an ophthalmologist had to go to a hospital or to a sight-testing 'optician'. The latter is a man who sells spectacles and professes to test his customer's sight. He may have no knowledge of refraction or may have picked up a little and usually is untrained in diseases of the eye. Ostensibly he charges only for the spectacles supplied. The greater part of the spectacles worn in this country are obtained in this way. The sight-testing opticians formed an organization which provided a sort of training and applied to the government for registration, which would have given them the position of legally recognized practitioners. A committee was appointed by the government to report on the matter. The British Medical Association opposed the plan, holding that only qualified ophthalmologists should be recognized as capable of dealing with defects of sight. The association's representatives were informed by the committee that while it agreed that in the best interests of the patient the examination of his eyes should be carried out by an ophthalmologist, legal recognition could not be withheld from opticians unless an ophthalmic medical service was organized for the poorer classes at a cost compatible with what they could afford. The British Medical Association realized that a wider issue than ophthalmic service was at stake—the legal recognition of nonmedical persons for medical service. An Association of Dispensing Opticians (who supply spectacles only on the prescription of ophthalmologists and do no testing) was already in existence. In combination with them was formed the National Ophthalmic Treatment Board which produced a scheme by which the poorer classes can obtain an ophthalmic medical examination and glasses for inclusive standardized charges. The examination is carried out by practitioners whose qualifications and experience in eye work have been investigated by the Ophthalmic Committee of the British Medical Association. If the eye condition found requires extended treatment, the patient's physician will be so informed and any further treatment by the ophthalmologist will be a matter for separate arrangement. The persons eligible for this scheme are all those who are state insured under the panel system and their dependents and noninsured persons unable to make their own arrangements with an ophthalmologist, whose total family income does not exceed \$1,250 a year. The fee payable to the ophthalmologist is \$2.50. The service he is required to give comprises examination and prescription of glasses, if required, including the use of a mydriatic in cases in which this is necessary. When glasses are ordered, the whole charge for them and the examination begins at \$3.50 for the frames of white metal and increases for more expensive frames. The National Ophthalmic Treatment Board has established national eye service centers in the principal cities in charge of the dispensing opticians who are required to exhibit to all patients a complete list of the board's ophthalmic practitioners, from which the patient makes his selection.

This scheme has been brought into existence to counter the attempt of sight-testing opticians to obtain state recognition. For the first time a national service has been established without aid from or control by the government. Though connected with the administration of the national insurance act the scheme is independent of it and unlike it is not in any way socialistic. The following example of its working is given by the *British Medical Journal*. Out of 120 persons

seen by one ophthalmologist, 2 had been previously seen as private patients but would have been unable to continue attendance except under the new service. One might have been able to afford a \$5 fee. The remaining 117 would have gone either to the hospital or to a sight-testing optician. Six were subsequently admitted to a hospital, and 80 needed treatment in addition to glasses. If these patients had gone to sight-testing opticians they would have been put off with glasses, and the other treatment needed would have been neglected.

The Recognition of Indian Medical Degrees

The medical degrees of Indian universities were first recognized for registration in Great Britain by the General Medical Council in 1892. From 1922 onward, recognition was accorded only for limited periods, being extended from year to year as a result of reports of inspectors appointed by the council to investigate the medical examinations. Then the ill feeling aroused by the Indian political agitation caused trouble. Indian nationalism expressed itself in the refusal of the Indian universities to allow inspectors appointed by the British Medical Council to inspect their examinations (*THE JOURNAL*, April 12, 1930, p. 1156). This was represented as an indignity, although the Council was only following the practice in operation for British universities and colleges. Registration gave Indian graduates the right to practice in Great Britain, and the council was in duty bound to satisfy itself as to the standards maintained in India. The refusal of inspection of examinations therefore compelled the council to withdraw recognition of Indian degrees pending the establishment of a system maintaining adequate standards. This aroused further resentment and an all-India medical conference, held at Simla in connection with the maintenance of proper standards in provincial medical schools, passed a retaliatory resolution recommending the admission to the Indian Medical Service only of men holding qualifications registrable in India (*THE JOURNAL*, Aug. 9, 1930, p. 423). The withdrawal of recognition of Indian degrees has made it difficult for Indian graduates to pursue postgraduate work in England and to secure employment in the British dominions and colonies. A result is that a bill is to be introduced in the Indian legislative assembly for the establishment of an all-India medical council that would restrict the medical register to graduates and exclude diploma holders who undergo a shorter course of training and whose standard varies so much that they would not be recognized in other countries.

London Hospital Services

In addition to its voluntary hospitals, London has a large number of municipal hospitals which used to be under the control of local authorities but now have passed under the London County Council, with the result that their service has become more highly organized and more efficient, approaching the high standard of the voluntary hospitals. The London Voluntary Hospitals Committee and the London County Council have cooperated in the preparation of a joint survey of voluntary and municipal medical and surgical services in hospitals, clinics and dispensaries, with a view to greater cooperation between the two systems. The number of beds in the voluntary hospitals is 14,833. The total number of new inpatients treated in 1931 was 216,788. These hospitals maintain 239 operating theaters, where 123,312 operations were performed in a year. New outpatients amounted to 1,596,361 and their total attendances in the year to 8,355,756. Arrangements have been made for linking up for undergraduate educational purposes certain municipal hospitals with the London medical schools.

In a letter to the *Times* Dr. G. C. Anderson, medical secretary to the British Medical Association criticizes the employment by the council of whole time physicians for attendance on the sick door as they are thus denied the right of choos-

ing their medical attendant. The association holds that the employment of whole time physicians for one section of the population—the destitute section—is wrong in principle and disadvantageous to patient and physician. It is on free choice of physician that the association bases its policy for a general medical service for the nation. The employment of the part time medical officer who is at the same time in general practice is open to less objection. Although free choice is not enjoyed by the patient, the physician is not the “poor man’s doctor” alone. The association asks for a scheme, comparable to the national health insurance plan, which will permit any one in receipt of public assistance, not an inmate of an institution, to choose his own physician from the local area.

A Tribute to Sir Robert Jones

The colleagues, patients and friends of Sir Robert Jones desire to pay a last tribute to his memory, in recognition of his great services to surgery and to a multitude of patients and also to recall his work in the Great War. It is proposed to establish a fund for this purpose, from which there will be benefactions to Liverpool (the city in which he lived and did most of his work), to the Royal College of Surgeons, and perhaps to other bodies with which he was associated. A joint letter supporting this tribute to “the greatest orthopedic surgeon of all time” has been published in the medical journals over the signatures of Lord Derby, chancellor of the University of Liverpool and secretary of state for war during the Great War, Lord Moynihan, Sir Holburt Waring, president of the Royal College of Surgeons, other leaders of the profession, and distinguished foreign surgeons, such as the Mayos, Arthur Steindler, W. C. Campbell, De F. P. Willard, Putti, Nove-Josserand and Murk Jansen.

PARIS

(From Our Regular Correspondent)

Feb 8, 1933

The General Assembly of Medicine

The Assemblée générale de médecine, which meets in Paris twice a year, differs from the conventions of the learned societies, since it is organized particularly for the practicing physicians of France who meet to report observations made among their clientele, generally rural. Previous assemblies have dealt with papers on cancer and tuberculosis. The recent session, presided over by Professor Mauriac of Bordeaux, chose “Undulant Fever” as the chief topic for discussion. Undulant fever has invaded nearly the whole French territory, and it may be discovered almost anywhere if a careful search is made. Often the disease presents mild or benign types that pass unnoticed. The most important foci, of sheep or goat origin, are in southern France. In the department of Bouches-du-Rhône, the mortality from undulant fever corresponds to that from typhoid fever, in the Vaucluse region, it tends to be even higher. In Pyrenees-Orientales, undulant fever is the most widespread disease of animal origin. In Lot-et-Garonne, which is some distance from these two foci, eleven cases have been reported. In Doubs, still farther removed, twenty-eight cases have developed in farmers caring for cows infected with infectious abortion. Undulant fever occurs now in the more central departments heretofore immune. It does not exist north of Paris, and it becomes more rare as one gets away from the highways commonly traversed by ambulant herds. Several departments in which sheep raising is an important industry are free of the disease. Undulant fever is brought about chiefly by direct contact with animals. It may originate from goats, sheep, cattle, horses or dogs. Man appears to be less receptive to *Alcaligenes abortus* than to *Alcaligenes melitensis*. Clinically undulant fever appears to present more serious complications at certain periods. In some years only general symptoms are noted, while of late one has observed

the invasion of the visceral organs, and the nervous and hepatic symptoms are assuming increasing importance. The hip joint is most commonly affected. The evolution of undulant fever extends over a long period (from seven months to two years) and develops in the form of paroxysmal attacks. The pain is difficult to combat, but the prognosis is generally favorable and recurrences are unknown. Although a protean disease, undulant fever sometimes simulates pulmonary tuberculosis, rebellious rheumatism, hepatitis and even a nervous disorder. A blood culture is the only sure biologic test. Serodiagnosis is valuable. As a form of treatment the physicians of Doubs recommend especially neoarsphenamine, while the physicians of Pyrenees-Orientales hold that protein therapy (injection of milk) gives the best results but at the price of severe general reactions. In Isère, more favorable results have been secured with vaccine. As to prophylaxis, the physicians of Aude emphasize the importance of educating the stock raisers, calling their attention to the significance of limping due to arthritis and to the importance of not housing goats and cows in the same stable and of never mixing their milk. On account of the part that ambulant herds play in disseminating the disease, the physicians of Vaucluse think that stricter regulations concerning their movements should be imposed. The physicians of Pyrenees-Orientales demand regulations controlling the migrations of ambulant herds, the cleaning of sheepfolds and the disposition of excrementa.

Physical Examination for Drivers of Automobiles

The question of a medical examination for drivers of automobiles has come up again before the Academy of Medicine, as a result of a communication from Professor Cazeneuve and Mr. Tanon, to whom is entrusted the medical examination of automobile drivers at the prefecture of police of Paris. This examination is compulsory in Paris for drivers of public vehicles having a seating capacity for eight persons. The ministerial decree of April 1, 1930, which established this examination, does not apply to the provinces, where there is an increasing number of public vehicles that carry a large number of passengers. Cazeneuve expressed his surprise at this laxness. On a previous occasion, these authors reported that the examination carried out at the prefecture of police had enabled them to eliminate applicants suffering from dementia paralytica, tabes, heart disease, and other incapacitating diseases. They submit proof that the occupation of automobile driver may, if the driver’s seat is inside or the car is poorly ventilated, bring on eye disorders, the prodromes of syncope, due to the action of gas fumes. Inequality of the pupils in some classes of professional drivers seems to occur in about 10 per cent of the subjects submitting to an examination. The fuel most used in France is composed of impure hydrocarbons—often of industrial benzol, sometimes mixed with denatured alcohol. Certain impurities, such as thiophene in the benzols may increase the toxicity, likewise carbon monoxide may be incriminated. The compulsory examination of automobile drivers is eminently desirable. The reason that it has not been more generally adopted is that there are several hundred thousand persons who would have to be examined. At the rate of 100 examinations a day, it would require several years to complete the process, and as the physicians making the examinations would have to receive a fee, it would require a large expenditure of money.

Ruins of an Old Temple

Excavations that have been made in Burgundy, at Saint-Germain Sources Seine, the source of the river that flows through Paris, have unearthed Roman ruins showing that this spot was formerly the site of important hot baths. Vestiges of a temple 70 meters long and 25 meters wide, dedicated to Dea Sequana, the goddess of the Seine, have been found. Excavations have revealed the existence of a reservoir 80 meters long and 25 meters wide, which, formed of concrete from 50 to

80 cm thick, held the water from various springs that fed it. It appears that these springs possessed a high medicinal value. The numerous ex-votos collected in the temple are evidence of this fact. For example, along with objects reproducing in bronze diseased members, such as eyes, hands, and even a woman's breast, there was found a head, carved in stone, of a bearded man, while near the right ear there was a protuberance that might represent a tumor, there was also a bronze depicting a case of orchitis in a young man. Formerly, therefore, the sources of the Seine were regarded as miraculous. Furthermore, up to the nineteenth century, Paris physicians attributed to the waters of the Seine, even when collected at Paris, remarkable therapeutic properties in diseases of the kidneys and the liver. They are strongly charged with calcareous salts, brought in by its principal tributary, the Marne. Today, owing to the sewage of many cities emptying into it, the Seine has become an immense sewer, the waters of which are dangerous—even for bathing purposes.

Opinions on the Effects of the Economic Situation on Health

The effects of the economic situation on health is one of the great questions for the heads of the public health service. It is interesting to note how medical officials of the *Krankenbassen* have expressed themselves on the question. In an industrial suburb of Berlin, the official has been unable to observe any unfavorable effects. He explains the unusually low morbidity by the fact that, under present conditions, there has been an increasing elimination of chronic patients from gainful occupations, which results in a more restricted selection of workers, from the standpoint of health. The reduced number of cases due to minor illnesses is a welcome effect growing out of present conditions. A medical official of central Germany points out that the morbidity among the unemployed is greater than that of insured members who are employed but that the unemployed are less inclined to report sick and hence give a false impression that the unemployed constitute a favorable risk. The true morbidity is not reflected in the figure showing incapacity to work but rather in the totality of cases of illness. Undue delay in consulting a physician is observed more frequently among the unemployed. Another medical official in the Rhineland notes that the group of persons who have remained at work is composed mostly of the more favorable risks, from the standpoint of health, and that because of the smaller number of persons employed, the number of accidents has declined. However the morbidity among persons receiving welfare aid has increased so that the total morbidity appears to be greater than formerly. There are also more frequent instances of premature enrolment among the class of invalids. A colleague in Bavaria has observed no evidence of increased transmission of diseases other than in the increased spread of disease in individual families. The psychopaths, weaklings and persons undergoing more or less rapid physical decay, since they seldom find employment are gradually being eliminated from the care of the sick benefit associations.

In Hamburg, while there has been a decrease in the number of persons reporting sick there has been an increase in the average duration of incapacity to work which was 35.91 days in 1930 and 40.66 days in 1931, and likewise an increase in the average period of hospitalization (35.0 days as against 32.3). The number of patients cared for by the welfare authorities is today usually greater than that receiving aid from the sick benefit associations. The reduced privileges as to hospital care for an insured member's family will doubtless result in some unfavorable manifestations. The bad conditions under which the unemployed live at least offset the absence of occu-

pational injuries. While it is doubtless true that formerly undue demands for medical aid were made, the present minimum of living requirements is sure to exert in the long run a damaging influence on health.

Finally, a hygienist of a commune points out that unemployment among men reduces exposure to tuberculosis almost to the vanishing point, whereas in women the good effects of enforced leisure are offset in some cases by domestic employment and repeated pregnancies, including many miscarriages. From this survey it will be seen that a uniform picture of conditions throughout the *reich* can hardly be gained, in spite of the good organization and honest attempts to facilitate a general survey of conditions.

Voluntary Work Service for Unemployed Young People

As a manifestation of the economic stress, particularly as it affects the youth, the idea arose of providing the younger generation an opportunity to direct their energies into healthy channels. Hence the federal government issued two decrees, as of July 23, 1931, and July 16, 1932, with a view to establishing what has been termed 'a voluntary work service.' The movement has met with a measure of success, for by Sept 1, 1932, 144,000 voluntary workers had been enrolled in this service. The question was first raised as to whether a voluntary work service or a legally established compulsory work service should be created, and it was decided in favor of the former. The voluntary work service makes its appeal to all young Germans, without distinction as to occupational or professional training, social position or political and religious views, belonging to the 18 to 25 age groups. A plan is being considered to create also a working year (or half year) for our university graduates. The number of young men belonging to these age groups (18-25) is placed at 4,000,000, although only 1,000,000 are actually unemployed. The work to be performed must be of a useful nature—for the most part in the country. The types of work chiefly considered are improvements, laying out of roads and paths, cultivation of waste lands, and the like. During their period of service, the work volunteers are insured against sickness and accident. The sponsors of the work are the authorities of the *reich*, the *länder*, the provinces, the circles (corresponding in general to the English county), the cities, and the welfare juvenile leagues. For every voluntary worker the federal government pays 2 marks a day (about 48 cents) to the respective sponsors of the work which the sponsors are required to expend (without deductions) in providing shelter, board, clothing and pocket money for the workers—usually for periods of twenty weeks, although in the case of important economic enterprises the time may be extended to forty weeks. A like sum (2 marks a day, Sunday excluded) is credited to the voluntary worker if he works for a longer period, and these credits may be used in acquiring a small tract of land as a homestead. Great importance is attached to the strengthening of the volunteer workers from physical, mental and moral points of view. Physical exercises, games and the like are provided to that end. Shelter is supplied in specially established camps. Special attention is given to the training of leaders. The conduct of the voluntary work service has been placed in the hands of a federal commissary, who is aided by the heads of the thirteen labor bureaus in the respective *länder*. For each voluntary worker about 1,000 marks, or \$238 is expended each year. On Aug 1 1932, the federal commissary had 50,000,000 marks, or \$11,900,000 at his disposal for this purpose. The details of the regulations affecting the voluntary work service have not yet been announced.

Vendors of Fraudulent Radium Apparatus

Vendors of fraudulent radium apparatus are becoming numerous, as may be seen from an announcement of the Hamburg Aerztokammer (chamber of physicians), which appeared also in the daily press. The Hamburg Aerztokammer has

been repeatedly informed of late that patients have been seriously injured and grossly cheated by irresponsible traveling salesmen who sold them so-called radium compresses, radioactive drinking water, radium beakers, radioactive inlay soles, and the like. The names and addresses of sufferers were procured usually at public gatherings at which the healing of all sorts of diseases was discussed. In a few instances, the agents assumed the role of physician or nurse. The patients received at ridiculously high prices preparations that could not possibly do what was promised, and that, for the most part, had no therapeutic value whatever in the disease in question, nor did they have any prophylactic value. Patients are therefore warned not to waste their money on apparatus that has only oratory and vain promises as a basis for its effectiveness.

ITALY

(From Our Regular Correspondent)

Jan 31, 1933

The Otoneuro-Ophthalmologic Congress

The third congress of the Società otoneuro-oftalmologica and the first congress of the Società radio-neurochirurgica were recently held jointly at Bologna. Professor Ceni spoke on the reactions concerned in the conception of vitalism. According to the vitalistic conception, all the manifestations of psychic and organic life, taken as a whole, consist of cerebral reactions indissolubly connected with one another and induced by external stimuli. The most important reactions are those originating by way of the organs of sight and hearing. Experiments conducted on deaf and blind animals by the speaker and his "school" over a period of forty years have demonstrated that, through the action of psychosensory traumas, there intervenes in animals a state of psychic impairment comparable to a true dementia and not unlike that which follows cerebral injuries. Strong arguments support the theory of the existence of absolutely distinct cerebral centers that are the seats of congenital and acquired forces. The congenital forces, which represent the impulses and the aptitudes peculiar to individual species (instincts), are always located in the anterior segments of the brain. The acquired forces are adapted, through the sensory stimuli from without, to the recognition and the evaluation of the images destined to stimulate the impulses, and are localized in the posterior segments of the brain.

SURGERY OF THE HYPOPHYSIS

"The Present Status of Surgery of the Hypophysis" was presented by Professor Cavina, who discussed the indications for the removal of the hypophysis, which consist essentially of tumors and of certain chiasmal syndromes of probable pituitary toxic origin, which the speaker was the first to describe. He explained the various routes suggested by surgery for reaching the hypophysis. On the basis of reasonably comprehensive statistics, he stated that the operative mortality and the recurrences (owing to the skill of experienced neurosurgeons) are comparatively low. The operation results in the recovery of sight and in the improvement of the symptoms of altered trophism. Radiologic treatment of hypophyseal tumors was first attempted in Italy in 1908 by Gramegna of Turin and has been found useful in certain types of slow evolution as supplementary to surgery.

Hirsch spoke on operative interventions on hypophyseal tumors by his transseptal method. He secured favorable results in a series of 233 cases. He was able to follow the history of fifty-seven patients for from four to thirteen years after the operation, and in forty-one of them there were no recurrences.

Palumbo explained the details of the technic of radium therapy in tumors of the hypophysis and the paranasal sinuses.

Verzella noted gradual improvement of the visual field in a patient affected with hypophyseal tumor and treated with

roentgen rays. He followed up this case for four years. He attributed the improvement to a diminution of the pressure that the anterior cerebral arteries exerted on the optic chiasm when the latter is pushed upward by a tumor.

OPTIC NEURITIS OF SINUS ORIGIN

The second topic, "Optic Neuritis of Sinus Origin," was presented by Professors Di Marzio and Ferreri. They operated on thirty patients with various lesions of the optic nerve and impairment of vision. The majority of the patients were relieved by opening the ethmoidal and sphenoidal sinuses, even those who presented no clinical or radiologic evidence of sinusitis. The improvement usually took place rapidly, sometimes within twenty-four hours. In some cases the improvement was gradual, extending over months or even years.

Weill presented a paper in which he classified the various types of retrobulbar neuritis into chronic forms found in diabetic patients, alcohol addicts and inveterate smokers, and optic neuritis proper. Of the forms without ophthalmoscopic signs, Weill distinguished two types, the typical and the atypical. Typical neuritis is generally unilateral and acute and occurs in persons from 15 to 35 years of age. It is often the first sign of multiple sclerosis. The atypical form is subacute and is sometimes bilateral, in addition to the central scotoma there is also a peripheral narrowing, often temporary, of the visual field. He stated that the typical forms heal spontaneously, while the atypical form may be improved by operation. Weill has observed, however, that many cases of atypical retrobulbar neuritis are not due to sinusitis but to disorders of the sella turcica, especially tumors about the optic nerve.

Giussani pointed out that sometimes the only clinical manifestation of a hyperplastic sphenoidal sinusitis is an impairment of the vision. Sometimes there are intense headaches associated with neuralgia and sympathetic disturbances.

Salotti examined 500 craniums radiologically, and found about 130 cases of chronic sinusitis. In the greater part of these he found that both the ethmoids and the sphenoids were involved.

Silvagni discussed the relation between the functioning of the hypophysis and the chronic inflammatory sinusitis. He found in most cases observed a hypofunction of the hypophysis, the significance of which has not as yet been fully explained.

Venereal Disease in the Army

In 1922 the Sanita militare adopted regulations designed to reduce the danger of contagion from venereal diseases among the soldiers. The regulations are based on the following principles: moral and hygienic training given to the soldiers, the creation in all barracks of special rooms for prophylaxis against venereal disease, protection of infected persons, and isolation and treatment of patients until they are not infectious. The results have been excellent. In 1921 the number of soldiers treated for the first time was 18,000 (5,000 of whom had syphilis), in 1922 the number so treated increased to about 12,000, and in recent years (from 1928 on) a total of about 5,000 new cases each year has been reported. The prophylactic measures adopted have given the most favorable results with syphilis, there were admitted to the military hospitals 4,811 patients in 1921, 3,245 in 1922, and 761 last year.

Professor Boveri

The death of Prof. Pietro Boveri, instructor in neuropathology at the University of Turin, is announced. He began his career in the University of Pavia and spent several years of study in the institutes of Paris and London. On returning to Italy he became department head in the Clinica delle malattie del lavoro, in Milan. During the war he served as director of neurologic centers in Alexandria and Genoa and later was called to the neurologic center in Milan. In addition to several works on clinical medicine he published several volumes on neurologic

subjects His contribution to the study of familial hypertrophic neuritis led to the recognition of a clinical form termed the "Pierre-Marie-Boveri" type. In syringomyelia, he described a peculiar change of the skin, which he termed "lizard skin" He called attention also to the presence of a subungual ridge in lesions of the median nerve His name is chiefly known to neurologists on account of the Boveri test with potassium permanganate applied to the cerebrospinal fluid

Professor Sanarelli Honored

The Faculté de médecine de Paris has conferred on Professor Sanarelli, director of the hygienic institute of the University of Rome, the degree of doctor honoris causa During the ceremonies at the Sorbonne, Professor Balthazard, dean of the faculty of medicine, recalled some of the principal researches of Sanarelli, namely, on typhoid, cholera and anthrax, the theory of heredo-immunity to tuberculosis, and the discovery of the ultrafiltrability of the virus through semipermeable membranes Professor Sanarelli was also recently appointed an honorary member of the society of tropical medicine in Paris

JAPAN

(From Our Regular Correspondent)

Jan 28, 1931

The Census for 1930

The national census taken in the fall of 1930 showed that the total population of the Japanese Empire was 90,396,045, according to official figures announced by the home office Of this total, 64,450,005 persons were registered in Japan proper 21,058,305 in Chosen, 4,592,537 in Formosa, and 295,198 in the Japanese portion of Sakhalin There were 330,000 more men than women in Japan proper In point of density of population, Japan proper had an average of 436 persons per square mile, while for the empire the figure was 346 per square mile Formosa came second with 330 inhabitants to the square mile, Chosen third, with 247, and Sakhalin last, with 24 Among the prefectures, Tokyo ranged first in density of population with 6,531 per square mile, while Hokkaido came last with 82 These figures are based on a total area for the empire of 260,704 miles In point of comparison, Java and Madura have a density of population of 836, Belgium, 686 England, 734, Germany, 345, France, 191 4, and the continental United States, 41 3 Japan's population classified according to age shows 23,502,000 persons below the age of 14 years, 35,827,000 between the ages of 15 and 59, inclusive, and 4,737,000 above the age of 60 The census figures indicated that in October, 1930, a total of 29,220,000 persons, or 45 6 per cent of the total population, were employed The following are the figures classified according to occupations agriculture 14,156,030, marine product industry 568,040, mining, 236,180, commerce, 4,463,110, industry, 5,290,560 communications, 1,108,560, domestic, 806,000 others, 2,592,070

Memorial Ceremony for the Late Baron Aoyama

Under the joint auspices of the Tokyo Imperial University Medical Department, the Japan Internal Disease Society and the cancer research institute a memorial ceremony was held, January 23 for the late Baron Dr Tanemichi Aoyama He is here regarded as the greatest physician that Japan has known in the past sixty years The ceremony was attended by more than 1,000 persons in the great hall of the Tokyo Imperial University He died fifteen years ago His followers now occupy most of the important positions in medical circles of this country He was the founder of the cancer research institute a member of the house of peers and a professor at the Tokyo Imperial University To commemorate the occasion important papers were read by Drs Mitamura, Tamura and Iurutake

The Number of Physicians

The excess of physicians and the turning out of more than 3,000 graduates from the medical colleges each year have been said to be the cause of the economic situation among the practitioners According to an official report, the total number of them at the beginning of 1932 was 49,681, of whom 45,582 were clinicians There were 7 07 clinicians per 10,000 of population Now, the number is 48,098, of whom 44,889 are clinicians This is a decrease of 1,583, of whom 1,493 are clinicians They are divided into

	1932	1933	Change
City practitioners	19,026	10,727	701 increase
Town practitioners	13,219	12,806	413 decrease
Village practitioners	13,337	12,356	981 decrease

The table shows that the remarkable decrease in towns and villages is a result of the concentration of practitioners in the cities The graduates of medical colleges this year also will be obliged to stay in the greater cities instead of going into the country The city practitioners will therefore have a harder time in the future, while the villagers will be left without doctors

Traffic Accidents in Tokyo

Tokyo sees fatal traffic accidents every day "Speeding up" is threatening the inhabitants Even street cars, which have long been complained of as being slow, are now speeding up The taxicabs dash hastily to and fro The metropolitan police bureau reports that there were 35,650 accidents in this city in 1932, 441 persons being killed and 21,068 badly hurt Compared with the previous year, the dead increased by 120 and the injured by 1,930 The chief offender is the motor-car, which causes 70 per cent of the accidents The business depression places cab drivers in severe competition, they overwork and become tired and weary and violate the speed limit The proportion of motor-cars is 1 to 250 persons

Feb 2, 1933

Statistics on Tuberculosis

The 1930 report of the director of the Amsterdam association for the combating of tuberculosis indicates that the regular decline of mortality from tuberculosis in Amsterdam and in the Netherlands as a whole has been continued The mortality rate of tuberculosis in Amsterdam is lower for men than for women There have been no changes in the organization of the consultation centers of the district A characteristic feature of this organization is the cooperation between the association, the physicians, the public health service and the ministry of labor As for methods employed, the attempt to search out all patients having open pulmonary tuberculosis has come to the fore The number of children treated with BCG vaccine increased in 1930, and no harmful effects were observed The general impression with regard to its value is favorable The results of the Pirquet reaction on 22,694 children, aged 0-14 for the years 1920-1930 and the year 1930, show that the percentage of positive reactions is diminishing every year

With reference to urban and rural tuberculosis, Dr Josephus Jitta has published some interesting figures The mortality rate in 1930 was only 7 31 per 10,000 inhabitants During the period 1921-1930, the decline in tuberculosis mortality was 50 per cent for the cities and 33 per cent for the rural districts The mortality from tuberculosis has increased considerably in children under 1 year of age

Public Health Congress

The thirty-seventh Public Health Congress, held in Amsterdam, comprised two sections the congress proper and the preliminary meeting of various health commissions, at which

the chief topic on the program was "The Removal and Disposal of Garbage in Small and in Large Communes." Professor Van Loghem emphasized that a modern system of garbage removal must meet the following conditions. It must cause no embarrassment to the community, it must be as economical as possible, and it must satisfy the needs of public health. The two systems that best meet these conditions are incineration and transformation into fertilizing material. Dr. Van Mannen described the system in use in The Hague. It consists in transporting the garbage to Drentha, where it is spread out and left for about two months to allow biologic processes to take place, it is then collected and sold to farmers for fertilizing purposes.

The congress proper dealt with the topic "Mental Hygiene." Dr. C. T. Kortenhorst spoke on welfare meetings designed to promote the mental health of the population. Dr. F. S. Meyers, in a paper entitled "A Communal Service of Mental Hygiene," described the organization that he founded in Amsterdam. Professor Van der Scheer emphasized the importance of organizations of this kind for the mental health of the people.

Association for the Study of Social Medicine

At the annual meeting of the Association generale pour l'etude de la medecine sociale, W. L. L. Carol spoke on "Infection of Man by Animals." One common infection is due to *Trichophyton faviforme-album*, which is communicated to man through contact with cattle or other domestic animals. Hammer spoke on "Cases of Sudden Death," which must not be confused with unexpected death and accidental death. The cases of sudden death are, for the most part, due to arteriosclerosis of the coronary arteries or to syphilis of the aorta.

The School of Medicine at Batavia

Prof. C. Bonne, president of the faculty of the school of medicine in Batavia, reports that the attendance at the school is increasing rapidly and on August 1 had reached a total of 313. The number of students entering the freshman class, after graduation from a secondary school, is increasing, the totals for the past five years having been 27, 33, 36, 62 and 67, respectively. If the number of admissions continues to increase at that rate, the school will have to be enlarged or the school at Surabaya will have to be transformed into a university. It is interesting how the students not supported by the government are distributed among the various races. Since the school opened, 62 Europeans, 92 Chinese and 82 natives have been enrolled. The Chinese are in the majority. By means of scholarships, the government exerts a certain compensatory influence. The important question is to find room and accommodations for such a large number of students. From the standpoint of the results of examinations, conditions are not so good as they are with respect to attendance. There are too many students who enroll before they receive an adequate secondary education. The Chinese are the most successful in passing their examinations. If things go on unchecked, before long the school will be graduating only Chinese physicians, a fact that merits the attention of every one.

Marriages

GERALD TRESLAR WATTERSON, Glenwood, Ind., to Miss Iona Mae Brandenburg of Connersville, February 14.

WILLIAM CHARLES BOSWELL, Macon, Ga., to Miss Doris Elizabeth Glisson, January 7.

LEON WATSON, Broadway, N. C., to Miss Anne Sheppard of Charlotte, January 25.

H. CROSKY ALLEN to Miss Helen Cuddy, both of Norristown, Pa., recently.

Deaths

Henry George Mehrtens ☉ San Francisco. Stanford University School of Medicine, San Francisco, 1913, acting dean and professor of medicine (neuropsychiatry) at his alma mater, member of the American Neurological Association, American Psychiatric Association and the Association for Research in Nervous and Mental Diseases, on the staff of the Lane Hospital, aged 49, died, February 28, of heart disease, following influenza.

Alexander E. Stepfield, Doylestown, Ohio, Homeopathic Hospital College, Cleveland, 1883, member of the Ohio State Medical Association, past president of the Wayne County Medical Society, formerly member of the school board and county coroner, aged 75, died, February 24, in the Akron City (Ohio) Hospital, of pneumonia, following an operation for gastric ulcer.

John Osgood Rush ☉ Mobile, Ala., Medical Department of the University of Alabama, Mobile, 1904, fellow of the American College of Surgeons, urologist to the City Hospital and Dispensary, Providence Infirmary, the U. S. Marine Hospital, and the Florence Crittenton Boys' Detention and Girls' Detention Homes, died, February 14, of heart disease.

William Taylor Logsdon, Wichita, Kan., University of Louisville (Ky.) School of Medicine, 1889, Chicago Homeopathic Medical College, 1902, member of the Kansas Medical Society, served during the World War, for many years on the staff of the Wichita Hospital, aged 74, died, February 13, of cardiorenal disease.

George F. Woodring, Bartlesville, Okla., Hospital College of Medicine, Louisville, Ky., 1876, member of the Oklahoma State Medical Association, on the staff of the Washington County Memorial Hospital, aged 76, died, February 24, of pneumonia, following phlebitis of the saphenous vein.

Samuel Ross Crothers, Chester, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1889, member of the Medical Society of the State of Pennsylvania, formerly mayor of Chester, aged 66, on the staff of the Chester Hospital, where he died, February 19, of Hodgkin's disease.

Emma Scribner MacKay Appel ☉ Chicago, Northwestern University Woman's Medical School, Chicago, 1901, for fifteen years medical examiner of the vocational guidance bureau of the board of education, aged 57, died, March 4, in the Women's and Children's Hospital, of cirrhosis of the liver.

Earle Harrison Coon, Excelsior Springs, Mo., Marion-Sims-Beaumont Medical College, St. Louis, 1903, member of the Missouri State Medical Association, served during the World War, aged 52, died, February 17, in St. Luke's Hospital, Kansas City, of peritonitis.

John Waterhouse Daniel, St. John, N. B., Canada, Bellevue Hospital Medical College, New York, 1865, M. R. C. S., England, 1867, formerly mayor of St. John, oldest member of the Canadian Senate, aged 87, died, January 12, of complications following influenza.

Joseph Robert Simpson ☉ Miami, Fla., Medical College of Virginia, Richmond, 1909, past president of the Association of Seaboard Air Line Railway Surgeons, on the staff of the Jackson Memorial Hospital, aged 51, was found dead, February 13, of heart disease.

William Henry Slocum, Long Branch, N. J., University of Pennsylvania School of Medicine, Philadelphia, 1892, served during the World War, formerly president of the board of health, aged 64, died, February 9, of chronic myocarditis and coronary thrombosis.

Gustav H. R. Schroepfel, Collinsville, Ill., St. Louis College of Physicians and Surgeons, 1892, member of the Illinois State Medical Society, aged 64, died, February 3, in St. Mary's Hospital, East St. Louis, of shock following a prostatectomy.

Addison Bybee ☉ Milford, Utah, College of Physicians and Surgeons, Medical Department of the University of Illinois, Chicago, 1906, on the staff of the Livermore (Calif.) Sanitarium, aged 56, died, Nov. 21, 1932, of influenza and pneumonia.

William Satterlee Leavenworth ☉ Surg., Lieutenant Commander, U. S. Navy, Mare Island, Calif., Medical School of Maine, Portland, 1916, entered the Navy in 1917, aged 42, died, Nov. 29, 1932, in San Diego, of meningitis and bronchopneumonia.

Edwin Elisha Swift, New York, Medical Department of the University of the City of New York, 1880, member of the Medical Society of the State of New York, aged 77, died, March 2, of arteriosclerosis and chronic myocarditis

John Howard Kauffman, St Paul, Medical Department of the University of the City of New York, 1884, formerly a druggist, aged 73, died, January 7, in St. Joseph's Hospital, of intestinal obstruction and mesenteric thrombosis

Arthur Leon Grover ♂ Reno, Nev Harvard University Medical School, Boston, 1903, member of the American Association of Pathologists and Bacteriologists, aged 56, died, January 28, of disease of the coronary arteries

George H Carey, Los Angeles, Hahnemann Medical College and Hospital, Chicago, 1900 member of the California Medical Association, aged 56, died, January 31, when he jumped from a ninth story window

Francis M Mueller ♂ Lawrenceburg, Ind, University of Louisville (Ky) School of Medicine, 1895, past president of the Dearborn-Ohio County Medical Society, aged 59, died, February 14, of heart disease

Horace Robert Skinner, Toppenish, Wash, Washington University School of Medicine, 1928, member of the Washington State Medical Association, aged 32, died, January 6 of bronchopneumonia

Max I Blowstein ♂ New York, University of Basel Medical Faculty, Basel, Switzerland, 1917, aged 41, died, January 31, in the Mount Sinai Hospital of acute yellow atrophy of the liver

James Franklin Hedrick, Weatherby, Mo, Barnes Medical College, St Louis, 1904, member of the Missouri State Medical Association, county coroner, aged 61, died, January 31, of heart disease

Dorothy Jean Burrows, Harriston, Ont Canada, University of Toronto Faculty of Medicine, 1922, aged 34 died, Dec 7, 1932, as the result of a peanut lodging in a bronchus early in September

Samuel Horace Littlefield ♂ Boston, Harvard University Medical School, Boston, 1892, aged 63, died, February 8, in the Brooks Hospital, Brookline, of carcinoma of the sigmoid and duodenal ulcer

Mitchell Walter, Bethlehem, Pa, Medico-Chirurgical College of Philadelphia, 1893 member of the Medical Society of the State of Pennsylvania, aged 65, died, Dec 5, 1932, of angina pectoris

Freeman Clarke Hersey, East Corinth Maine Medical School of Maine Portland 1873 member of the Massachusetts Medical Society, aged 90, died, February 4, in Bangor, of pneumonia

William James Harvey, Jr, Philadelphia Howard University School of Medicine Washington, D C, 1910, on the staff of the Mercy Hospital, aged 47, died, February 6, of heart disease

Benjamin Rulon Smith, Cambridge City, Ind, Starling Medical College, Columbus, Ohio, 1870, Civil War veteran aged 90 died, February 10, of arteriosclerosis and cerebral hemorrhage

Louis Philippe Howe, San Francisco, Medical Department of the University of California San Francisco 1908 fellow of the American College of Surgeons, aged 52, died, January 20

William Bullard Jordan, Ocala Fla Atlanta Medical College, 1915 member of the Florida Medical Association and the South Carolina Medical Association, aged 40, died January 17

John Eugene Stinson, Chickasha Okla University of Nashville (Tenn) Medical Department 1870 Confederate veteran aged 84 died February 17, of pneumonia, in Oklahoma City

John J Trichel, Houston Texas Eclectic Medical University Kansas City Mo 1903 aged 52 died January 31 in the Park View Hospital, of injuries received in an automobile accident

Francis S Stevenson, Aurora Mo Beaumont Hospital Medical College St Louis, 1888 member of the Missouri State Medical Association, aged 73 died February 10, of heart disease.

Christopher May Thornton, Rovalton Ill Louisville (Ky) Medical College 1876 member of the Illinois State Medical Society aged 82 died February 9 as the result of a fall

Robert Purnell Floyd, Louisburg, N C, Medical College of the State of South Carolina, Charleston, 1878, formerly member of the state legislature, aged 78, died, January 10

Thomas Cottrell Brooks, Los Angeles Illinois Medical College, Chicago, 1904, member of the California Medical Association, aged 58, died, January 9, of cerebral hemorrhage

Jacob Goldberg, Buffalo, University of Buffalo School of Medicine, 1885, for fourteen years chairman of the board of education, aged 69, died, February 22, of coronary thrombosis

Hannes Inberg, Danville, Va, Bennett College of Eclectic Medicine and Surgery, Chicago, 1906, aged 53, died, January 27, of heart disease, on a train, while enroute to Philadelphia

Adolph Roos ♂ Forest Park, Ill, Rush Medical College, Chicago, 1887, aged 74, died, Dec 23, 1932, at his home in Oak Park, of cardiac hypertrophy with decompensation

Thomas Henry Blow, Calgary, Alta, Canada, McGill University Faculty of Medicine Montreal, Que, 1895, aged 70, died suddenly, Dec 27, 1932, in Vancouver, B C

Maurice Moray Armstrong ♂ Los Angeles, University of Southern California College of Medicine, Los Angeles, 1902, aged 59, died, February 6, of agranulocytic angina

John Thomas Kimsey, Latihop, Mo, University Medical College of Kansas City, 1899, member of the Missouri State Medical Association, aged 80, died, January 22

William Oliphant Stewart, Guelph, Ont, Canada, University of Toronto Faculty of Medicine, 1888, for many years member of the school board, died, Dec 25, 1932

Hugh M French, Yakima, Wash, Tennessee Medical College, Knoxville, 1897, member of the Washington State Medical Association, aged 60, died, January 16

George Gaston Lewis, Lakewood, N J, Medical Department of the University of the City of New York, 1888, aged 66, died, February 13, of cerebral hemorrhage.

Marvel Smith Lingo, Newark, Md, University of Pennsylvania School of Medicine, Philadelphia, 1910, aged 44, died, February 22, in a hospital at Salisbury

George Wesley Peart, Burt, Mich, Detroit College of Medicine, 1893, served during the World War, aged 62, died, January 22, in St. Mary's Hospital, Saginaw

John Henry Sweet, Jr, Newport, R I Harvard University Medical School, Boston, 1898, aged 58, died, January 17, in the Newport Hospital, of pneumonia

William J C Corse, Baltimore, University of Maryland School of Medicine, Baltimore, 1872, aged 87, died, Dec 21, 1932, in the Sheppard-Enoch Pratt Hospital

John Newell Waggoner, Canton, Mo Yale University School of Medicine, New Haven, Conn, 1909, aged 48, died, February 11, of a self-inflicted bullet wound

Buchanan Caldwell, Biggs, Calif, Medical Department, University of Tennessee, Nashville, 1887, aged 76, died, January 15, of chronic interstitial nephritis

Arthur Hamilton Schuyler ♂ Rochester, N Y, Albany (N Y) Medical College, 1905, aged 50, died, February 17, of a self-inflicted bullet wound in the head

Mortimer Jesurun, Long Beach, Calif, Medical Department of the University of the City of New York, 1892, aged 72, died, January 31, of cerebral hemorrhage.

Carter Weisiger, Cumberland, Va, University College of Medicine, Richmond 1896 member of the Medical Society of Virginia, aged 57, died, Dec 30, 1932

Green W Campbell, Hazard, Ky, University of Louisville (Ky) School of Medicine, 1911, aged 55, died, February 12, in the Hazard Hospital, of nephritis

James G Clyne, Lakewood, Ohio Cleveland Medical College, 1876, aged 83, died, February 15, of injuries received when he was struck by an automobile

Raymond G Richards ♂ Grand Rapids, Mich, Rush Medical College, Chicago, 1901 on the staff of the Butterworth Hospital aged 54, died, January 24

William Harry Nelson ♂ Ruskin, Neb, University of Illinois College of Medicine, Chicago, 1910, aged 59, died, February 25, of coronary thrombosis

Parley Leon Holman ♂ Mount Pleasant, Utah, Washington University School of Medicine St. Louis, 1923, aged 41, died Nov 1 1932, of heart disease

Victor Sterki, New Philadelphia, Ohio University of Berne Faculty of Medicine Berne, Switzerland, 1878, aged 86, died January 25 of arteriosclerosis

Charles Rush Gray, Trenton Fla, Loyola University School of Medicine, Chicago, 1918, aged 42, was found dead in bed February 1, of heart disease

Frank Lambert King, Omaha, Pulte Medical College, Cincinnati, 1888, aged 72, died, January 12, in St Luke's Hospital, of gangrene of the foot

Emil Theilmann, Kansas City, Mo., Kansas City Homeopathic Medical College, 1897, aged 68, died, Dec 28, 1932, of carcinoma of the colon

Allan Lincoln Shirley, East Bridgewater, Mass., Medical School of Maine, Portland, 1890, aged 68, died, February 20, of coronary thrombosis

Guy Filby Palmer, Ucluelet, B C, Canada, McGill University Faculty of Medicine, Montreal, 1885, aged 70, died suddenly, January 4

Hervy C Way, Long Beach, Calif., College of Physicians and Surgeons, Keokuk, Iowa, 1887, aged 82, died, January 10, of arteriosclerosis

James E Elliott, Detroit, Detroit College of Medicine, 1901, member of the Michigan State Medical Society, aged 58, died, January 23

James H Atlee, Chattanooga, Tenn., Jefferson Medical College of Philadelphia, 1886, served during the World War, died, January 31

Thompson Seiser Westcott, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1886, aged 70, died, January 28

Walter V Havens, Headleys Corners, Ohio, Starling Medical College, Columbus, 1886, aged 73, died, Dec 18, 1932, of heart disease

John Wesley Smith, Burlington, Iowa, Barnes Medical College, St Louis, 1903, aged 63, died, February 18, in the Mercy Hospital

Marcus Lafayette Bryant, Pulaski, Ky., University of the South Medical Department, Sewanee, Tenn., 1906, aged 79, died, January 9

George F Whitney, Pottsville, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1883, aged 68, died, Dec 25, 1932

Horace Ray Elliott, Niagara Falls, Ont., Canada, University of Toronto Faculty of Medicine, 1902, aged 52, died, Dec 19, 1932

Henry Juren, Oklahoma City, University of Halle, Germany, 1878, aged 82, was found dead in bed, Nov 7, 1932, of heart disease

Andrew Haig, Campbellford, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1891, aged 66, died, Dec 6, 1932

James Osborne, Redwood City, Calif., University of Glasgow Medical Faculty, Glasgow, Scotland, 1872, aged 84, died, January 4

Alva Claude Surber, Muncie, Ind., Baltimore Medical College, 1895, aged 61, was found dead, January 27, of poisoning

Catalino Nicolas, Manila, P I, University of St Thomas College of Medicine and Surgery, Manila, 1892, aged 62, died recently

John Albert Couch, Toronto, Ont., Canada, Faculty of Medicine of Trinity College, Toronto, 1885, died, January 11

Robert Lee Hackworth, Coral Ridge, Ky., Hospital College of Medicine, Louisville, 1889, aged 70, died, January 11

Samuel Houston Clemons, Chattanooga, Tenn., Meharry Medical College, Nashville, 1909, aged 55, died, January 18

Louis Herman Grunig, San Francisco, Hospital College of Medicine, Louisville, Ky., 1895, aged 71, died, January 24

Frances Sarah Conaway Saunders, Los Angeles, Iowa Medical College, Des Moines, 1886, aged 80, died, Dec 9, 1932

Wilson McKenery Moore, Los Angeles, Jefferson Medical College of Philadelphia, 1904, aged 57, died, January 21

George E Davis, San Francisco, Hahnemann Medical College of Philadelphia, 1873, aged 86, died, January 30

Frederick Albert Schock, Los Angeles, Medico-Chirurgical College of Philadelphia, 1889, aged 65, died, January 8

Thomas Hamilton Payne, Friendship Ind., Louisville (Ky.) Medical College, 1871, aged 88, died, January 5

Robert H Reeves, Paulsboro, N J, Jefferson Medical College of Philadelphia, 1883, aged 72, died, January 7

James H Ashlock, Glendale, Ky., University of Louisville School of Medicine, 1875, aged 76, died, January 13

Thomas A Wood, Bybee, Tenn., Chattanooga (Tenn.) Medical College, 1898, aged 63, died, January 13

Thomas Nelson Kraus, Lenoir City, Tenn. (licensed, Tennessee, 1889), aged 73, died, January 1

Correspondence

CORRECTION OF PROGNATHISM OF THE LOWER JAW

To the Editor—Recently my attention was called to a communication by Dr Robert H Ivy (THE JOURNAL, Dec 31 1932) criticizing an article by Pettit and Walrath (THE JOURNAL, Dec 3, 1932). Apparently his perusal of this article was hasty or casual. In the references quoted he proves that this is really a new procedure for the correction of prognathism, and at the same time he shows an unfamiliarity with either his own references or with our article. The operation of Dufourmentel, to which he refers, is entirely different, is a destructive procedure, shortens the total length of the ramus and its appendages, leaves a flail joint structure with a definite disturbance of muscle attachment, and from an anatomic consideration creates the "makings" of the unfortunate open bite. None of these disadvantages exist in the technic which Walrath and I advocate.

He refers to my statement that in operations heretofore described the bone fragments after section are fastened together with wire or plates or other foreign material. As proof of this, I quote his own writings and need only refer to the textbook by Blair and Ivy (of which he is co-author) "Essentials of Oral Surgery," published by the Mosby Company in 1926, wherein he makes the following statement: "We would not dispense with the lower fixation (of the bone fragments) in this operation. *Proper fixation* here consists of fastening the cut bones with silver wire or chromicized catgut at their lower borders."

Dr Ivy's conception of a temporomandibular arthroplasty may be the destructive procedure of a removal of the mandibular head and neck, embodying the destruction of important anatomic structures. The real surgical temporomandibular arthroplasty does not do this but instead consists of the making of a new joint by a fibrous union in the neck of the condyle, accurately constructed, permitting a backward bow without displacement, without shortening of the ramus, without interference with muscle attachment or function, without destruction of anatomic form. This type of temporomandibular arthroplasty was advocated by Murphy for ankylosis only. We are now advocating it for prognathism and those mandibular displacements wherein a double joint with the resulting increased motion will so readily restore any deformity caused by some unnatural relationship of the mandibular body and its ramus.

JOSEPH A PETTIT, M D, Portland, Ore

INSTRUMENTS OF PRECISION—AND EXPENDITURE

To the Editor—In the diagnosis of disease the physician relies on a number of scientific factors. Most important of these are (a) the past history of the patient, (b) his present history, (c) his symptoms and (d) the signs. These are of increasing scientific importance in the order given.

On the signs of disease the modern physician stakes most of his clinical skill, his confidence in them being won by the fact that they are objective in character, while the symptoms of the patient are subjective. To evaluate the importance of signs accurately, the physician resorts to instruments of precision when his analysis of the case needs logical support. Thus, various physical and chemical examinations demonstrate signs more clearly that might escape detection by the naked human senses.

For several reasons these instruments of precision have a special interest for the hospital administrator. First of all, though not the most important reason, they represent an item of expense in purchase and in maintenance. The tendency to

lean on them for the purpose of saving time and error in clinical judgment is greater than it ever was among medical men inside the hospital, whether the patient can afford it or not, and outside the hospital, if the patient can afford it. On theoretical grounds, at least, no one can take issue with the physician when he orders roentgenograms, cardiograms, metabolism tests and other expensive physical, chemical, bacteriologic and serologic examinations in progressively greater quantities from the laboratories. Hard times do not stay the march of scientific progress, the physician would rightly argue, and therefore the hospital must bow to the inevitable if it would maintain a progressive scientific standard of diagnostic service. The tactful administrator could, of course, ask the medical board of the hospital to express an opinion on subjects like these. It is more than possible that they, under the sobering influence of financial stress, might be willing to accept the limitation of expensive diagnostic tests to those cases authorized by the senior members of the staff, and then only after careful clinical inquiry as to need. The intern who orders x-ray films taken of "all the long bones" during the course of the "work-up" of a case on the chance that one of them might be the seat of a metastatic growth in a case of advanced cancer might be able to make out a fair case for scientific research but not for any routine advantage in the care of the patient, who might indeed miss something important when the doctor assigned to him depends too much on instruments of precision and too little on his clinical senses.

But it is not with the financial aspect of cost alone that we are concerned. The prick of a needle for the purpose of drawing a drop of blood for examination is mild compared to the indiscriminate use of the cystoscope, the bronchoscope and the vaginal speculum (to mention only a few) in sensitive human beings. Just how much meddling there is with the therapeutic laws of nature no one can say, perhaps because no one will, nor is the administrator privileged to question the scientific practices of his medical staff. But the medical board, which presumably consists of the elders of the medical staff, should be consulted freely in doubtful cases when the administrator, who enjoys their confidence, may be surprised to learn how much they will be able and willing to control improper, harmful or wasteful examinations that can bring small good to any one, even in an educational or investigative way.

E M BLUESTONE, M D, New York

Director, Montefiore Hospital

WOHLFAHRTIA MYIASIS

To the Editor—In THE JOURNAL, February 18, I note an article on Wohlfahrtia Myiasis in North Dakota. Since the authors state that the search of the literature fails to reveal another identified case involving the eye, may I call attention to the fact that in the American Encyclopedia of Ophthalmology, volume XII, page 9350, is an article I wrote on parasites.

This states that the oldest recorded case of ophthalmomyiasis was recorded by Salzman in 1718. It gives a brief account of a child whose eyes had both been destroyed by maggots. More recent cases in 1853 and 1903 are briefly described with references in that article. Others might be cited concerning Wohlfahrtia. All these cases are in children and involve the eye.

This flesh fly is widely distributed violent in its attacks, and not infrequently chooses the eye. Reported cases are frequently in children however others on record involve adults even 67 years of age.

Persons resting or sleeping in the open air during the warmer part of the day are especially exposed to danger of being infected.

HENRY B WARD, Urbana, Ill

Professor of Zoology and Head of the

Department, University of Illinois

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CONTRAINDICATIONS TO SPINAL PUNCTURE

To the Editor—Please state the contraindications to making spinal punctures for diagnosis. Please omit name. M D, Texas

ANSWER—Infections of the soft tissue through which the needle must be inserted, such as erysipelas or cellulitis of the back, constitute a contraindication to spinal puncture. If there is a local infection in the lumbar region and cerebrospinal fluid must be removed for diagnosis, some other route, such as the cisternal or ventricular (in infants), should be used.

Deformity of the spine in the lumbar region constitutes a contraindication to spinal puncture, as there is danger of breaking the needle. In cases of caries of the spine, especially if due to a tuberculous infection, spinal puncture is contraindicated, not only because of the deformity but also because there is danger of producing a meningitis by accidentally inserting the needle into the diseased soft bone and releasing organisms into the subarachnoid space.

Spinal puncture should not be done during a convulsion, as the sudden release of pressure may cause herniation of the brain and death. In addition, there is also danger of breaking the needle. It is therefore desirable to wait until the convulsions have ceased before spinal puncture is attempted. If the convulsions are continuous, it may be necessary to give an anesthetic before doing the puncture. In tetanus, spinal puncture is not contraindicated but is often hard to perform without an anesthetic, because of the rigidity of the spine.

There is no uniformity of opinion as to whether or not spinal puncture is contraindicated in cerebral hemorrhage and in brain tumor. Most neurologists believe that massive recent intracranial hemorrhage in the adult constitutes a contraindication to spinal puncture, especially if the hemorrhage is thought to be due to small ruptured aneurysms of the vessels of the brain or to hemorrhage of the middle meningeal artery. The removal of cerebrospinal fluid, it is argued, may disturb the clot and start a fresh hemorrhage. Most pediatricians do not consider this objection to hold good in intracranial hemorrhage of the new-born.

Some neurologists hold that brain tumor, especially one in the neighborhood of the third ventricle and at the cerebello-pontile angle, constitutes a contraindication to spinal puncture, because of the danger of herniation of the brain. Others, however, do spinal punctures in cases in which brain tumor is suspected or is known to exist. Spinal puncture should be done with caution in all cases of brain tumor, and only small amounts of fluid should be removed.

It is inadvisable to do a spinal puncture in any of the exanthems as for instance in scarlet fever, although a report has been published of a large series of cases in which cerebrospinal fluid was removed by the lumbar route in a number of such cases, with apparently no ill effect.

The question as to whether or not spinal puncture is contraindicated in septicemia has not yet been settled. It has been found by several observers that in some cases of septicemia the mere removal of cerebrospinal fluid may cause a meningitis. However, if only a small amount of the fluid is removed slowly, spinal puncture is not only permissible but often indicated.

LOSS OF SALT AND WATER BY PERSPIRATION

To the Editor—I have just read with much interest the editorial on perspiration and sweat in THE JOURNAL, Dec 3 1932. Many years ago when hot and tired and sweating from bicycling I discovered that a draft of common table salt in a glass of water was far more refreshing and invigorating than any of the drinks I could get along the road. Now when golfing (at 72) and sweating and when plain water at the fountains does not seem to go anywhere or relieve thirst I find that the addition of salt is a prompt and noticeable stimulant. I have often wondered whether phosphates would not be even better but the commercial phosphates are sweetened and leave a drugstore taste. Does the Na of the salt take part in neutralizing the acidity of fatigue or does the NaCl supply only the salt lost in the sweat? Any comments will be very acceptable.

H C. WORTHINGTON M D Oak Forest, Ill

ANSWER—Profuse sweating results in a loss not only of considerable volumes of water but also of surprisingly large quantities of salt. It is well known that the physiologic integrity of the neuromuscular mechanism is highly dependent on the presence of inorganic ions, some of which exert specific effects but the sum total of which controls the normal osmotic

relationship in the organism. A rapid dilution of intravascular and interstitial fluids diminishes the osmotic pressure with the result that, until readjustment is made either by ingesting salts or by excreting the excess water, subjective symptoms occur varying from mild fatigue and lassitude to actual muscular cramps in man and convulsions and death in experimental animals. Among stokers, iron workers and miners, such cramps occur in individuals who, during severe sweating, drink large quantities of water. It has been shown that the seizures do not occur if salt solution is consumed instead of water, furthermore, appetite is maintained and a feeling of vigor and freshness after the hard day's work has been noted.

These observations confirm those of the correspondent. The beneficial effect of salt solution is due to the replacement not only of fluid volume but of salt as well. As recent studies show that relatively little of the acid of sweat is neutralized by base, the favorable influence of salt appears to depend largely on its replacement of a depleted supply. There is so little phosphate lost in sweat that it seems doubtful whether this compound would exert the beneficial effect of sodium chloride.

EROSION AND DECAY OF TEETH IN DIABETES

To the Editor—A man, aged 53, has had diabetes since 1924 and has been taking from 40 to 50 units of insulin daily since then. His condition is entirely satisfactory except that he has noticed that the four upper incisors have eroded to such an extent that at present the condition is not only unsightly but also interferes with mastication and speech. The other teeth have also shown some erosion but not nearly as much as those mentioned. He does not use a pipe or a cigaret holder. A number of dentists have informed him that it was most unusual even in a diabetic patient to have the incisors erode so rapidly and to such a degree. All report porcelain jackets the only corrective measure. I take it that the condition is caused by the loss of certain chemical properties of the teeth and probably by the diabetes. I also realize that, in the case of the incisors, the only measure remaining is corrective dentistry. What is the cause and what can prevent this condition occurring in the remaining normal teeth? Please omit name.

M D, Florida

ANSWER—It is not clear from the description that this is erosion, it may be gingival-third decay. However, it is assumed that it is erosion and not decay. Its connection with diabetes is not noted in the American literature, but Romer and others describe it as one of the mouth complications of that disease, involving usually the anterior teeth, incisors, cuspids and premolars. The causation is hidden in obscurity, mechanical factors, disease of the adjacent labial or buccal mucous and parotid glands, disorders of metabolism and exposure of the necks of the teeth to acids have been mentioned. It is more common in high-strung subjects under conditions of high nervous and mental strain. Consumption of excessive amounts of grapes and citrus fruits are frequently associated with erosion. Incorrect and overzealous brushing of the teeth with abrasive dentifrices should be given consideration. The disease runs a fluctuating course and may undergo a spontaneous remission. Prevention is concerned with the elimination, as far as possible, of the items listed, especially excessive brushing with abrasive dentifrices. Ordinary fillings are not satisfactory, although in favorable cases, if the margins can be widely extended, they may serve a useful purpose. Perhaps the best practice is to delay this form of treatment until the defects are of such a character as to require porcelain crown restorations, as in this case. Extreme sensitiveness of the dentin at the base of the defect can be controlled by the application of some such drug as silver nitrate. Treatment and prevention, because of the uncertainty as to the etiology, are, at the best, largely experimental and far from satisfactory.

TREATMENT OF DANDRUFF OR SEBORRHEIC DERMATITIS

To the Editor—What is the best method of handling a bad case of dandruff? In this case it is truly a seborrheic dermatitis. Scabs form on the scalp in three or four days and there is a similar dermatitis between the shoulders. The only thing that has ever afforded any relief has been frequent washing. If not washed every few days, the scalp itches intensely and there is a continuous downpour of dandruff (epithelial debris, as the "cosmetologists" call it). Please omit name.

M D, Texas

ANSWER—On recently inflamed areas of seborrheic dermatitis it is desirable to use soothing lotions or ointments, such as used in acute dermatitis. From the brief description, it is assumed that the scalp will tolerate a pomade such as salicylic acid, from 5 to 10 grains (0.3 to 0.65 Gm), precipitated sulphur, 10 to 20 grains (0.65 to 1.3 Gm), petrolatum or liquid petrolatum, 1 ounce (30 Gm). This is applied daily to the scalp. As soon as improvement begins, it can be applied every second or third day. By care in parting the hair and rubbing in the

pomade, it can be applied to the scalp with little greasing of the hair. When the hair becomes greasy from the use of such an application, it should be shampooed, a liquid soap is most convenient for this, but any toilet soap may be used.

On the back ointments furnish the best form of application in seborrheic dermatitis. The applications for non-hairy skin should be weaker than those used on the scalp. The following is a good formula: salicylic acid, from 5 to 10 grains (0.3 to 0.65 Gm), precipitated sulphur, 10 to 30 grains (0.65 to 2 Gm), ointment of zinc oxide, 1 ounce (30 Gm). This should be applied twice a day and allowed to grease the underwear, so that slight application is constant.

LOSS OF ENAMEL FROM DECIDUOUS TEETH

To the Editor—A child of 15 months has the normal number of erupted teeth. The upper incisors have no enamel at all and have been gradually broken and worn away to short stumps. The process has been going on about six months. When first erupted, they were covered with enamel. At present they do not cause pain and there is little inflammation of the gum, there being none at all except around the upper incisors. A sister, aged 3 years, has large areas of caries on the upper incisors on the labial surface. There is no gingivitis. The mother, aged 25, has begun getting caries in the upper incisors on the outer surface. Her teeth with this exception are perfectly formed and she says that her "double teeth" are her deciduous teeth. The children were breast fed until 9 months of age, and have received cod liver oil since the age of 2 months. They live on a farm and have plenty of milk and green vegetables. The children received little sunshine the past summer because of weather conditions and "neighbors." Is the condition hereditary, a congenital defect in formation, and lack of vitamin D? What is the prognosis as to the permanent teeth? What treatment would you suggest. All appear perfectly normal otherwise. The 15 month child is walking and very active. Kindly omit name.

M D, Washington

ANSWER—Occasional cases are seen in which the deciduous teeth are worn away rapidly, regardless of the presence or absence of well formed enamel. There is no evidence that this is due to lack of proper formation of the teeth. Possibly the most encouraging statement is that this condition of the deciduous teeth seems to have no relation to the permanent teeth, which are likely to be normal. The fact that the mother's deciduous molar teeth are retained, which probably indicates that the bicuspid of the permanent set are missing, suggests the possibility of a shortage of bicuspid in the dentures of her children.

The dentist should take the best possible care of the deciduous teeth of the children, at least until it is definitely determined that the bicuspid are present.

ALLERGY TO QUININE

To the Editor—A boy, aged 6, is allergic. The sensitiveness manifests itself by urticaria and skin rashes. The causative agent has not been determined but it is nonseasonal. He has chronic malaria with the following blood picture: red blood cells 3,950,000, white blood cells 10,400, hemoglobin 58 per cent, polymorphonuclears 31 per cent. There is no past history of his taking quinine. He was given quinine in doses of 2 grains (0.13 Gm) three times a day in the form of a chocolate flavored quinine preparation (the patient is not sensitive to chocolate or cocoa) and after the third dose a diffuse skin rash developed with excessive itching over the entire body. I should appreciate any suggestions as to how to handle this case.

FRANCIS E. SULTZMAN, M D, Hannibal, Mo.

ANSWER—When a patient with malaria develops urticaria after taking quinine, it is almost certain that the patient has an idiosyncrasy (hypersensitiveness) to that drug. To give more quinine would probably be inviting further trouble, as he might then develop symptoms of bronchial asthma or rhinitis, in addition to the urticaria. An intracutaneous injection of 0.02 cc of a 1:1,000 dilution of quinine sulphate, along with a control test with physiologic solution of sodium chloride, for example, can be made and would probably be positive for the quinine.

Fortunately, as shown by W. T. Dawson and F. A. Garbade (*Idiosyncrasy to Quinine, Cinchonidine and Ethylhydrocupreine*, THE JOURNAL, March 8, 1930, p. 704), quinidine can be substituted for quinine. Those who are hypersensitive to quinine (the levorotatory alkaloid) can safely take quinidine (its dextrorotatory isomer). Therefore the boy should be given quinidine sulphate instead of quinine. The dose of quinidine sulphate should be small at first (about 2 grains, or 0.13 Gm), it can then be gradually raised to as much as 30 grains (2 Gm) daily, because of its slowing effects on the heart muscle, caution should be exercised. It should not be used at all in cases of cardiac decompensation. If quinidine is not available, one can dissolve quinine in water and add a little dilute hydrochloric acid.

PLACENTAL WASSERMANN TESTS OR CORD BLOOD EXAMINATIONS

To the Editor—Will you please furnish me with statistics concerning the reliability of placental Wassermann tests obtained at the time of delivery. At the Long Beach Community Hospital we are taking placental Wassermann tests as a routine procedure. How much more accurate would tests be taken on the mothers before delivery? If the latter should be adopted as a routine, would there be any advantage in continuing the placental tests also?

THEODORE A STRANG MD Long Beach Calif

ANSWER.—It is assumed that by "placental Wassermann tests" is meant cord blood examinations. There is far from being any general agreement as to the dependability of cord blood Wassermann tests. Browning and Mackenzie (Recent Methods in the Diagnosis and Treatment of Syphilis, London, Constable & Co, 1924, p 240) report Wassermann examinations on cord blood of eighty-eight cases in which either the infants or the mothers were syphilitic. Of this number, thirty-one gave positive and fifty-seven negative reactions. Kolmer (Serum Diagnosis by Complement Fixation, Philadelphia, Lea & Febiger, 1928, p 499) asserts that while a negative Wassermann reaction is inadequate evidence of the absence of syphilis, a positive reaction means syphilis in both mother and child. Williams (Obstetrics, New York, D Appleton & Co, 1930, p 749) reports 1 per cent false positive Wassermann reactions in a group of 5,000 cord blood examinations. He considers also a negative reaction as undependable in eliminating syphilis. Cord blood is apt to be anticomplementary, which may help explain the limited value of the Wassermann results reported. Data are presented in a recent report (*Arch Dermat & Syph* 26 597 [Oct.] 1932) in which the Kahn reaction proved superior in sensitivity and specificity to fourteen different Wassermann methods but no mention is made of this reaction in cord bloods. Serologic tests on the mother's blood during pregnancy cannot take the place of examinations of cord blood, which represents the fetal circulation.

PREGNANCY IN YOUNG GIRL

To the Editor—1 A few days ago I was called to see a child scarcely 14 years of age who the mother thought had appendicitis. Examination revealed a seven months pregnancy which the child admitted. She also confessed that her brother 18 years of age was the cause of the pregnancy. What I desire to know is: What are the chances that the child has of normal delivery? I could not take her pelvic measurements at the time and I have not seen her since. 2 Will the baby show signs of degeneracy of mind and body? 3 Am I compelled by law to report this case of incest to the proper authorities? Please omit name.

MD Ohio

ANSWER—1 The chances that this child has a normal delivery are good. Easily 80 per cent of such cases do not result in dystocia, that is, of course, if the pelvic measurements are normal.

2 There is no reason why the baby should suffer in mind or body unless one or both parents have signs of degeneracy. So far as we know there is no law compelling physicians to report such cases.

HYPERTROPHIC SCARS OF PALM OF HAND

To the Editor—Kindly let me know what the latest treatment of hypertrophic scar of the palmar surface of the hand is. It is of eight months duration and is about 3 inches long. Kindly omit name.

MD New York.

ANSWER.—The treatment of hypertrophic scars of the palmar surface of the hand depends on the cause, the width of the scar, and the presence or absence of a resulting contraction of the fingers. Narrow scars tend gradually to soften and diminish in size and are best left alone.

If the scar results from a drawing in of tissues from the surrounding area following the loss of a considerable amount of tissue, it is often wise to excise it completely, permit the tissues that have been drawn in to return to their normal position and then fill the defect immediately with a full thickness graft of skin the exact size of the defect itself. Such a graft can be obtained from the thigh or the abdominal wall.

INJECTION OF VARICOSE VEINS OF ABDOMEN

To the Editor—I have a patient with a mass of varicose veins on the lower part of the abdomen just above the pubes. Would it be safe to inject these with sodium morrhuate the same as I would if they were on her leg?

C W LION MD Ellinwood Kan

ANSWER.—The appearance of varicosities above the pubic region suggests an obstruction in the iliac or femoral vein on the same side. No mention is made of the history of a deep thrombosis, which was followed by abdominal varicosities. But

even in the absence of such a history, small pelvic clots, so-called silent clots, which accompany childbirth, may be responsible for collateral venous dilatations. The questions that must be answered, before an obliteration of these varicosities may be safely undertaken, are as follows: 1 Is there a latent pelvic phlebitis present, which could be activated by injections? A thorough pelvic examination must be made. Tender, palpable clots in the parametrium, vague, low abdominal pain aggravated by changes in the weather are suggestive of "resting infection" in the pelvic veins and contraindicate obliterative treatment, at least for the time being. 2 Has the original obstruction been overcome by canalization and other channels, or are the abdominal veins still functioning as active collaterals? To answer this question, the direction of blood flow in the abdominal varicosities must be studied. If a reverse flow—that is, toward the lower extremities—can be demonstrated, the new veins are superfluous and may be obliterated. The treatment of this type of varicosity requires considerable experience and should be undertaken with caution.

MIGRAINE WITH OCULAR PRODROMALS

To the Editor—In 1916 while I was undergoing considerable eye strain my vision suddenly became blurred as if atropine had been instilled. At that time I was 19 years old and in good physical condition. This blurring lasted for about two hours. The next day while writing an examination the same condition recurred. I insisted on writing and in a few minutes could not read at all. At that time refraction revealed astigmatism of 0.25 diopter at 90 degrees and glasses were prescribed. The same blurring recurred about eleven months later. The glasses were made slightly stronger and the blurring recurred about eight months later. The new glasses worn for close work only, were about +0.5 diopter. This blurring recurred more frequently and began to leave me with a dull occipital headache lately several times a week. The ophthalmologists have blamed the liver—the difference in strength between the adductor and abductor muscles and so on. Examination during this blurring does not disclose anything. The pupils are not dilated there are no hemorrhages. Mostly this blurring occurs while reading looking at the light from a window or looking away from bright to dark and vice versa. It still lasts about an hour and leaves me feeling bad for the rest of the day with the dull occipital headache. Physically there is nothing wrong and my habits are regular. The last correction was Right +50 Cyl axis 90 Left +12 Sph +37 Cyl axis 90. Please advise diagnosis and treatment. Kindly omit name.

MD Michigan.

ANSWER.—Judging from the symptoms, this sounds much like a case of mild migraine with ocular prodromes. If that is the case, the eyes have nothing to do with the cause of the blurring, which is now believed to be accounted for by a spasm of the retinal arteries. A certain percentage of cases of true migraine can be relieved by the use of cannabis, phenobarbital or other measures. A course of treatment in the hands of a competent neurologist is suggested.

HYPOTHYROIDISM AND ARRHYTHMIA

To the Editor—Please inform me whether you know of any book, medical journal or references to the effect of hypothyroidism on the disturbance in the rhythm of the heart or the pulse beat. I have Du Bois's 'Basal Metabolism, Berkeley's 'Endocrine Medicine', Wiggers' 'Circulation in Health and Disease', Vaquez and Laidlaw's 'Diseases of the Heart and Falta's 'Endocrinology'. These are not explicit enough or complete.

MD, Texas

ANSWER.—There is no cardiac arrhythmia that is the result of hypothyroidism per se. Arrhythmia may be present in a case of hypothyroidism but it is a function of some other disturbance than the hypothyroidism itself. The pulse is most frequently slow in this condition.

TESTS FOR SYPHILIS

To the Editor—1 Is the Wassermann test on blood from the umbilical cord dependable? 2 Is the Kahn test dependable? ('cord blood') 3 Does ether or nitrous oxide anesthesia have any effect on either test?

F E CLOW MD Wolfboro N H

ANSWER.—1 A dependable Wassermann method generally gives dependable results also on cord blood. The serum from such blood shows a mild tendency toward nonspecific fixation of complement (anticomplementary action), which the serologist can readily overcome.

2 The Kahn test, not being influenced by anticomplementary properties of serum, is generally accepted to give dependable results with cord blood.

3 No extensive studies are available on the effect of anesthesia on the serology of syphilis. Studies carried out soon after the development of the Wassermann test indicated that transient positive reactions resulted on blood obtained soon after anesthesia. In recent years, with improvements in tech-

nic, serologists have reported that anesthesia does not affect the dependability of reactions. The length of exposure to an anesthetic may be an important factor, a brief exposure might have no effect, while prolonged exposure might. It is therefore well not to depend on a serologic reaction unless repeated examinations several days or a week after anesthesia give the same results.

USE OF CURARE

To the Editor—I cannot find information as to what dilution of curare to use in experimental work as to the effects of the drug on muscle tissue. I should judge the solution used should be quite weak, and I should like to know where to procure it. Are there antidotes for this poison?

FFED E DARGATZ, M D, Kinsley, Kan

ANSWER—Curare is used in the laboratory in a 1 per cent suspension faintly acidified with acetic acid (shake label). When so prepared, an active preparation does not deteriorate rapidly. It has no action on muscle tissue but causes, in effective doses, paralysis by acting on the "receptive substance" at the myoneural junction. Germany was the American source of the crude drug prior to the war. For practicable purposes it is virtually unobtainable at present. Sometimes crude curare may be obtained from old pharmaceutical houses whose shelves contain a few grams—relics of a past age. Physostigmine (eserine) is the antidote for curare poisoning. Since the drug is rather rapidly destroyed in the body, artificial respiration should be practiced if there has occurred a paralysis of the diaphragm.

SALIVATION

To the Editor—What treatment would be most likely to be distinctly beneficial in the case of excessive salivation in the case of a man, aged 67, a cigaret smoker, whose lower teeth have all been removed? He has tried various remedies but particularly Bellafoline, manufactured by the Sandoz Chemical Works of Basel, Switzerland. While this preparation has been slightly beneficial, it is not sufficiently so and there is also some apprehension that the continuous intake of from four to six tablets a day of this preparation may possibly prove injurious in other directions. The salivation is most excessive in the afternoon and evening. Please omit name.

M D, Massachusetts

ANSWER—Salivation may occasionally be due reflexly to some gastro-intestinal condition. Generally, however, it is due to some local condition, as oral infection, a poorly fitting plate, or a peculiar sensitiveness to the rubberized portion or metal of the plate. Excessive smoking may cause salivation. It would be advisable to search for and remove any of these factors and in the absence of these restrict the smoking more or less. Bellafoline owes its virtue to its content of belladonna, which might be preferably prescribed in the form of the tincture or the active principle atropine. Bellafoline has not been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies.

ALBUMINURIA IN PATIENT WITH TUBERCULOSIS

To the Editor—In the routine urine tests of a woman, 33 years of age who has active tuberculosis I have invariably found from 0.5 to 0.75 per cent albumin (Esbach test). Seeded over the entire surface of the albuminous precipitate there is a thin layer of a resin-like brown flaky material. Will you kindly tell me what it is and its meaning?

TECHNICIAN, Pomona, N Y

ANSWER—It is difficult to say what this "flaky resinous" material may be. It would be possible for an excess of phenols and polyphenols to produce dark brown picramic acid in the presence of an alkaline urine. The administration of salicylates, phenyl salicylate, or similar compounds would furnish these substances in abundance, or they may be present as a result of intestinal putrefaction. An excess of bile pigments or uric acid may also be crystallized out of the Esbach's reagent as brown flakes, but the concentration would of necessity have to be greater than is usually found. In any event it is of little consequence compared to the existing albuminuria.

USE OF MORPHINE INTRAVENOUSLY

To the Editor—Are there any contraindications to the administration of morphine sulphate intravenously when the need for a prompt action is present? Please omit name.

M D, New York.

ANSWER—No. For instance, in urgent cases Mahenke (*Zentralbl f Chir* 1925, number 38) advises the intravenous instead of subcutaneous injection of morphine, in a dose of from 0.01 to 0.02 Gm, which produces a prompt effect lasting for about twenty minutes. The only untoward symptom experienced was vertigo, which resulted when the injection was given too fast.

Book Notices

The Scientific Basis of Evolution By Thomas Hunt Morgan Ph.D D.Sc. LL.D. Professor of Biology California Institute of Technology Cloth Price \$3.50 Pp 286 with 42 illustrations New York W W Norton & Company Inc 1932

This volume consists of twelve chapters, each of which is the substance of a lecture, somewhat expanded but essentially as delivered. These lectures, the Messenger Lectures, were delivered at Cornell University in the spring of 1931. The author, a leading geneticist, makes it his prime object to point out the contrast between truly scientific theories of evolution and various speculative theories. He asserts that "evolution is not so much a study of the history of the species as it is an investigation of what is taking place at the present time." He thus limits the truly scientific study of evolution to the field known as genetics. In this field alone, he asserts, is it possible to apply the really scientific methods of experiment and accurate analysis that are characteristic of the physical sciences. The facts and theories of genetics are presented simply, ably and attractively. No one else has done this so well. Some, however, still believe that paleontology, embryology and comparative anatomy may afford some truly scientific basis for the study of evolution and are not to be put aside as inferior disciplines. Morgan pins his faith almost exclusively to the gene theory of evolution, of which he is the originator. He comes close to discarding natural selection, utterly puts aside the Lamarckian theory, explains away orthogenesis theories, and shows no sympathy at all with vitalistic views, considering vitalistic such theories as emergent evolution, holism and organicism. He is the high priest of a large and prominent group of worshippers at the shrine of the gene theory. According to them, the genes are all powerful. In one place, Morgan makes the extreme hereditarian statement that "there can be little doubt that down to the minutest details our physical characters are due to inheritance." Throughout the book the author defends the mechanistic interpretation of life and ridicules metaphysical and vitalistic interpretations of life and evolution. The book was a Scientific Book Club selection and well deserves that distinction, for it is one of the most scientific books about evolution that has yet appeared.

Organic Chemistry for Medical Students By George Barger M.A. D.Sc. F.R.S. Professor of Chemistry in Relation to Medicine in the University of Edinburgh. Cloth Price 12/6 Pp 249 with illustrations London & Edinburgh Gurney & Jackson 1932.

The author's preface clearly states that the purpose of this admirable summary of facts is to meet the special requirements of the medical student as the ever increasing burden of the curriculum makes condensation of the essentials highly desirable. This purpose has been fulfilled. The work is highly condensed is full of important facts, and presents the material in simple language. There is almost no discussion of chemical theory or of the electrical mechanisms of chemical reactions. Because of the absence of any discussion of theory the book is particularly applicable as a textbook for teaching, when the

instructor can supply this deficiency. As such a textbook, the work can be employed most profitably. No discussion has been made of colloids, of the relationships of changes in hydrogen ion concentration, and of dyes having medical significance. In view of the modern trend in biochemical investigations, these omissions are unfortunate. The chemistry of the purines and of thyroxine is splendidly clear, the chemical relationships of salicylic acid and the salicylates are presented with admirable thoroughness. The book should prove excellent for the medical student desiring a condensed collection of essential and vital facts concerning organic chemistry as it relates to medicine, it is not a book of reference and does not pose as such. The type is clear and large, and structural formulas are clearly indicated. The index is adequate.

The Youngest of the Family His Care and Training By Joseph Garland M.D. Physician to Children's Medical Department Massachusetts General Hospital. Cloth Price \$2 Pp 196 with 11 illustrations Cambridge Harvard University Press 1932

This is one of the better books on the care of the baby prepared to aid mothers in caring for the infant. It is clearly and simply written and contains a great deal of material that the mother will find most useful. The book would be greatly improved by the inclusion of more illustrations and by the omission of several prescriptions that have been included. The principles outlined in this book will, of course, aid the mother in keeping her child strong and healthy. Unfortunately, the many mothers who need the type of advice contained in a book of this sort are unable to avail themselves of this material either because they are unable to read and understand it or for economic reasons.

Diseases of the Nose Throat and Ear for Practitioners and Students Edited by A Logan Turner M.D. LL.D. F.R.C.S.E. Consulting Surgeon Ear and Throat Department Royal Infirmary Edinburgh. With the collaboration of J S Fraser M.B. F.R.C.S.E. Surgeon to the Ear and Throat Department Royal Infirmary Edinburgh W T Gardner M.C. M.B. F.R.C.S.E. Aural Surgeon Eye Ear and Throat Infirmary Edinburgh J D Lithgow M.B. F.R.C.S.E. Surgeon to the Ear and Throat Department Royal Infirmary Edinburgh G Ewart Martin M.B. F.R.C.S.E. Assistant Surgeon Ear and Throat Department Royal Infirmary Edinburgh and Douglas Guthrie M.D. F.R.C.S.E. Surgeon to the Ear and Throat Department Royal Hospital for Sick Children Edinburgh. Third edition. Cloth Price \$6 Pp 465 with 269 illustrations Baltimore William Wood & Company 1932

All that has been said about the previous editions of this deservedly popular manual is applicable to this one. The clarity, conciseness, excellence of illustration and authority of statement make this textbook one of the best of its kind in the English language.

The Relative Value of Radiotherapy in the Treatment of Cancers of the Upper Air Passages By W Douglas Harmer M.A. M.B. M.C. University of London. Semon Lecture. Delivered at the Royal Society of Medicine on November 5 1931. Cloth Price 6/- Pp 85 with 15 illustrations London John Murray 1932

This booklet opens with a discussion of the general principles underlying radiation therapy. The author calls attention to the marked difference in results reported by various surgeons in the treatment of early, intrinsic cancer of the larynx by laryngofissure. The percentage of recurrences varies between 12 and 35. For carcinomas absolutely localized to one vocal cord or band, Harmer uses a modification of Ledoux's operation (fenestration) and applies radium through a window cut in the cartilage. When the growth has crossed the midline the radium needles must be placed bilaterally. Tracheotomy is not performed when the opposite vocal cord is movable and the glottis is adequate. In case of doubt, the front of the trachea is exposed and left ready for tracheotomy if necessary. This operation was performed on forty-seven patients with only one death. Eight cases suitable for thyrotomy were treated by the fenestration method with radium. Seven of the patients are living and free of disease after from two to six years. Twenty patients suffering from a more advanced stage of the disease were treated by this method with the following results. One patient remained free of disease for six years, a second has been well five years, four have been well for two years, and one is well less than one year after the operation. Harmer concludes that irradiation is the best treatment for all cases of intrinsic cancer of the larynx, and that the reported unsatisfactory results of irradiation are due to faulty technic, inadequate dosage and filtra-

tion, and underestimation of the extent of the disease. In the author's hands the percentage of cures in operable cases appears to be at least as good by radium as by surgery. For the borderline group, Harmer advises that radium always be tried before laryngectomy. The voice results after radium treatment are superior to those obtained by surgery. For carcinoma of the antrum the author gives a preliminary treatment with x-rays and one week later he performs a biopsy. The tumor is exposed by removing the hard palate with the alveolar process. The growth is removed by diathermy, and radium is inserted in the cavity usually by means of a mold. Of fifty-three patients treated by this method only ten are living, but many of the patients suffered from advanced stages of the disease. The results of irradiation in the treatment of carcinomas of the nasopharynx and tonsil, especially by means of large radium bombs (telerradium) and Coutard's method with x-rays are discussed. Harmer believes that there is a great future in the radiotherapy of malignant tumors affecting the upper air passages but that radium should be used only by specialists, preferably in special clinics. He concludes that palliative relief can be afforded by irradiation to a large percentage of patients suffering from advanced cancer with little danger and that it is safer to treat the more virulent types of cancer by combined irradiation and surgery than by surgery alone.

Cancer Then and Now New York City Cancer Committee American Society for the Control of Cancer Paper Pp 80, with illustrations New York Chemical Foundation Inc 1932

Education of the public remains one of the important phases of cancer control. The transmission of the necessary medical information to the layman presents peculiar difficulties. In this pictorial pamphlet the New York City Cancer Committee has succeeded admirably in translating highly technical material into everyday language in an interesting and attractive manner. The booklet contains much useful information. In a series of brief but direct communications, authors whose names are well known have commented on causation, early diagnosis, surgery, x-rays and radium in cancer. These statements are at once highly practical and scientifically accurate. Particularly attractive and valuable are the historical aspects dealing with the development of surgery, x-rays, radium, nursing, social service, and cancer hospitals. The illustrations constitute an historical atlas and it is a pity that they could not have been reproduced to better advantage. This publication is an example of what can be accomplished in cancer education without arousing undue fear of the disease. Although it was compiled primarily for the layman, the physician will find in these pages much information of historical interest and value.

Chirurgie du sympathique pelvien en gynécologie Par Gaston Cotte professeur agrégé à la Faculté de médecine de Lyon Paper Price 45 francs Pp 318 with 38 illustrations Paris Masson & Cie 1932

Almost the entire book is devoted to a discussion of the indications and technic of surgery of the sympathetic pelvic nerves, particularly resection of the presacral nerve. In the first three chapters the author discusses the history of this type of surgery and the anatomy and physiology of the pelvic sympathetic nervous system. Then follows the section on technic, which includes descriptions and illustrations of intervention on the periarterial plexus, the visceral plexus, the lumbosacral sympathetic chain and the communicating branches. Among the usual indications for this form of therapy the author includes pelvic pain associated with inoperable carcinoma of the cervix, dysmenorrhea, dyspareunia, vaginismus, painful cystitis, functional disturbances of the bladder, persistent leukorrhea, nymphomania, frigidity, pruritus vulvae, amenorrhea and trophic disturbances of the female genitalia. Among the rare indications he includes uterine pains during pregnancy, tuberculous peritonitis and salpingitis, and other ailments. The author maintains that he has obtained excellent results in the foregoing disturbances by resecting the sympathetic pelvic nerves. He has had an extensive experience, for since 1924, when he performed the first resection of the presacral nerve, up to July 1931, he performed 125 of these operations for menstrual irregularities alone. The book is well written and beautifully illustrated and is an excellent guide for those who care to undertake these operations. The

author's list of indications, however, is far too generous, for many of the conditions cited as indications can be remedied without surgical intervention. After all, every laparotomy, no matter how simple, entails some risk and should be avoided if there is a less hazardous method of therapy.

Pneumolyse Intrapleurale L'opération de Jacobæus et la thoracocautère d'après Maurer dans le pneumothorax artificiel Par le Dr Louis Sayé professeur à la Faculté de médecine de Barcelone Preface du Pr Léon Bernard Paper Price 40 francs Pp 239, with 119 illustrations Paris Masson & Cie 1932

This lucid, well illustrated and authoritative monograph is one of a series entitled the "Bibliography of Phthisiology" published under the direction of Leon Bernard. In the preface Bernard writes that radiology, bacteriology and serology, experimental and social medicine, surgery and chemotherapy have, so to speak, turned upside down the perspective of phthisiology, making of it a veritable specialty, and these monographs are designed to trace its development and bring the knowledge of its various aspects to the present time. In this volume on intrapleural pneumolysis, Sayé sketches the history of endoscopy as applied to the abdomen and to the thorax. In a series of tables on the published results of artificial pneumothorax, he shows that incomplete collapse due to pleural adhesions is its chief limitation. He deals systematically with the pathologic anatomy of pleural adhesions and the open operation for their severance, with thoracoscopy and thoracocautery, with the roentgen recognition of types of adhesions, and with the results following the use of the original Jacobæus operation and the operation as modified by Maurer. He gives in detail his results in 102 operations with the Jacobæus-Unverricht thoracoscope and includes eighteen illustrative case reports. A chapter follows on the use of gold salts in conjunction with the use of artificial pneumothorax and a final one on the thoracoscopic severance of adhesions. A bibliography is appended. This volume is recommended to all who are interested in the subject of intrapleural pneumolysis.

The 1932 Year Book of Radiology Diagnosis Edited by Charles A. Waters M.D. Associate in Roentgenology Johns Hopkins University Therapeutics Edited by Ira I. Kaplan B.Sc. M.D. Director Division of Cancer Department of Hospitals City of New York Cloth Price \$6 Pp 750 with 498 illustrations Chicago Year Book Publishers Inc 1932

For the busy physician who must make the most of leisure hours, a year book of radiologic progress is a welcome addition to the periodical literature on medical advances. This collective review of the latest literature covers roentgen diagnosis, roentgen therapy and radium therapy. An adequate review of such rich material, already presented in condensed form, is out of the question, but the opportunity may be utilized to commend in highest terms the project and the satisfactory manner in which it has been carried out. In radiologic diagnosis the important advance has occurred in ventriculography, encephalography, hepatosplenography, roentgen pelvimetry, and studies of the heart and aorta. In the alimentary tract, stress is laid on the "relief" studies by coating the mucosal surfaces with a small quantity of opaque solution, sometimes combined with air insufflation. In radiation therapy the most important communications relate to the need of supervoltage x-ray apparatus and radium packs, the necessity for which is by no means agreed on. Neither massive radium packs nor million-volt x-ray apparatus are available in any but endowed institutions. In fact, the English have found the 4 Gm radium bomb of insufficient value, the Radium Commission of the British Empire Cancer Committee stating that "the use of the bomb in its present form is not only uneconomic but unwarranted." The results of the large radium pack therapy, now being tried in several large clinics both in the United States and abroad, are being awaited with interest and some impatience. Standardization of a unit of dosage for roentgen therapy is an important accomplishment of the last year or two. The r (equivalent to about 25 R as established in France by Solomon) is now internationally accepted as the unit of x-ray measurement. The massive dose of roentgen therapy delivered in daily fractions so that the treatment is completed within two or two and a half weeks, as advocated by Coutard, is now being accepted and used almost universally as the method of choice in cancer of the larynx, upper air passages and nasopharynx. Preoperative as well as

postoperative irradiation in breast cancer seems to be the logical recommendation in the light of recently published results. As yet, no curative effect in carcinoma of the digestive tract has resulted from irradiation either by radium or by x-rays

Medicolegal

Workmen's Compensation Act Traumatic Neurosis —

In the course of his employment, an employee fell, striking the lower part of his abdomen on a hand truck. He was laid up for four or five weeks, during which time he received compensation. Then he worked for about ten months, but he quit because his condition was growing worse. A herniotomy was performed, but apparently he received no relief. Although an application for further compensation was rejected, he did not appeal from the decision. About eighteen months later, however, he filed a new claim, alleging that since the prior hearing he had developed "a post traumatic neurosis" as a result of the original injury and was totally and permanently disabled. He was awarded compensation and his employer appealed to the Supreme Court of Nebraska. His employer first contended that the claimant was barred from recovering compensation, by the former proceedings. But, said the Supreme Court, two physicians testified that the claimant's condition might be latent and is of a progressive nature, and that it was not discovered until shortly before the present action was instituted, and under the Nebraska workmen's compensation act, when an injury is latent is of a progressive nature and culminates in compensable disability, a claim may be filed within a year after its culmination. The condition for which compensation is now asked, "a post traumatic neurosis," was not involved in the former proceedings. The employer's contention that the claimant's present condition was not caused by the industrial accident, according to the Supreme Court, was disproved by the evidence. One physician testified that he had seen the claimant about fifty or sixty times since the injury and that his present condition was the direct result of that injury. Another physician testified that there was a definite proximate relation between the injury and the employee's present condition and that there were no intervening factors to account for that condition. No physician testified to the contrary. Accordingly, compensation was awarded the employee.—*Marler v Grainger Bros (Neb)*, 243 N W 622

Testimony of Medical Expert as to Probable Consequences of Injury—The plaintiff was struck by a truck and suffered a compound depressed fracture of the skull. He was taken to a hospital, and a piece of skull about the size of a silver quarter, which was pressing on his brain, was removed. Later he sued the defendant, the owner of the truck for damages. A neurologist, who had not attended the plaintiff but who had examined him three times prior to the trial, testified over the defendant's objections that the plaintiff had sustained a 50 per cent mental impairment and that epilepsy would probably follow. The testimony with respect to the present mental condition of the plaintiff, the defendant contended, should have been excluded, since it was predicated partly on "the history of the case," which included hearsay statements by the plaintiff and others, as well as the physical evidence of the injury. But, said the Supreme Court of Appeals of West Virginia the neurologist's opinion was based on the physical evidence as disclosed by the hospital records (supported by the testimony of the operating surgeon), x-ray examinations by himself his wide experience as a neurologist and the fact testified to by other witnesses, that the plaintiff was mentally normal before the injury. A medical expert properly qualified may testify as to the probable future consequences of an injury provided the consequences anticipated are such as in the ordinary course of events may reasonably be expected to happen and are not merely speculative or possible. The evidence of lay witnesses on the mental condition of the plaintiff was admissible. Ordinary witnesses when qualified by adequate observation may testify as to another's mental capacity.—*Graces v Katskin* (11 1 a) 164 S E 796

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

 Comfortable and Sanitary Colostomy Bag E. R. Arn, Dayton, Ohio—p. 541

Urinary Calculi—According to Randall, phosphoric acid 1 per cent has a pH acidity of approximately 1.6. Its bactericidal value is based on this. Phosphoric acid 1 per cent is practically isotonic and is slightly less acid than the gastric acidity after a test meal. In experimental dogs, renal pelvis injected with 1, 3 and 5 per cent phosphoric acid fail to show any destruction of the pelvic lining epithelium or damage to the renal papillae. Eleven patients in whom renal pelvic lavage with 1 and 2 per cent solution of phosphoric acid has been used, through a postoperative drainage tube, through a ureteral catheter, or through both, have not experienced discomfort or excessive renal pain. The bladder is less tolerant than the ureter or kidney pelvis, and the urethra is the least tolerant of all. The renal pelvic urine in recorded cases has been restudied and with one exception has been found to retain a normal acidity following this postoperative lavage. This step in prophylactic treatment in cases of recurrent renal calculi has a rationale in both correlated conditions in the lower urinary tract and in bacteriologic observations. The author concludes that, by bladder lavage with phosphoric acid postoperatively, alkalinization and phosphatic encrustations can be prevented. The treatment of staphylococcal cystitis, encrusting cystitis, leukoplakia and allied conditions by this means is indicated. The prevention of recurrent renal calculi of the phosphatic variety is being attempted with every indication of success. The possible dissolution of small phosphatic calculi, or fragments left at operation, may be expected by the recognized action of such strengths of phosphoric acid in vitro, and the tolerance of such topical applications in vivo. As a postoperative prophylactic measure against infection with the alkaliphilic organisms, it is herein proved safe and efficacious in kidney surgery and should therefore aid in the prevention of recurrent renal calculi of the phosphatic variety.

Pulmonary Tuberculosis—Coryllos states that collapse therapy is indicated only in the caseous form of tuberculosis, and only after the period of consolidation is over when the necrotic material has been sloughed out. In the extremely acute period of tuberculosis any collapse therapy is useless, because of the impossibility of collapsing a consolidated lung and because exudative tuberculosis generally heals by itself, it is dangerous because of the frequency of the occurrence of spontaneous pneumothorax. Pneumothorax if it does not produce selective collapse is useless and harmful and should be replaced by more efficient collapse therapy. Phrenicectomy is unable by itself to produce a definite cure of tuberculous cavities. It is useless in the other forms of tuberculosis. Associated with other collapse methods, it may be of real help. Intrapleural pneumolysis by the method of Jacobæus, in well selected cases and skilfully performed, can give good results. Extrapleural apicolysis with or without compression of the apex by foreign bodies is a method that is especially indicated in bilateral cases. Thoracoplasty is the most efficient method for permanent and definite collapse of the lung. It is, however, a major operation, requiring a faultless technic, a careful selection of cases, adequate preoperative preparation and painstaking previous estimation of the resistance of the patient, ether anesthesia is harmless but should be administered by such methods as to allow a complete separation of upper and lower respiratory tract and permit the suction of the bronchial exudate. Intratracheal anesthesia fulfils these requirements. The most important postoperative complications are cardiopulmonary complications generally following bronchial or bronchiolar obstruction and the resulting atelectasis and anoxemia. The treatment of pleural complications varies according to the nature of the exudate, it should be conservative in aseptic tuberculous exudates. Thoracoplasty is the treatment of choice. Injection of aromatized oil or dyes is to be tried in moderately infected empyemas, drainage should be installed in mixed infections and more especially in anaerobic empyemas later followed by thoracoplasty. Thoracic surgery in tuberculosis requires the close cooperation of the thoracic surgeon with the phthisiologist, not only before but also after operations, tuberculous patients should no more be considered as medical or as surgical patients but as medicosurgical cases requiring continuous medicosurgical supervision, study and treatment. Pulmonary tuberculosis can be successfully treated "by mechanical means," as Carson prophesied. This part of the problem is solved. What remains to be done is to perfect one's technic and to devise some means by which mortality will be decreased and operative indications enlarged.

Effect of Viosterol in Experimental Fractures—According to Grauer's experiments on guinea-pigs, viosterol, in therapeutic doses, causes stimulation of the osteogenic layer

of the periosteum in experimental fractures Osteogenic differentiation is enhanced through the agency of viosterol (vitamin D) Overdosage produces stimulation of the fibrous layer of the periosteum, through decalcification of bone, and causes retardation in repair Osteitis fibrosa is simulated by overdoses of viosterol in guinea-pigs Studies of the serum calcium and phosphorus in the case of high doses invalidate the calcium phosphorus product as a means to prognosticate non-union The author advances a theory as to the mode of action of viosterol in experimental fractures whereby the osteogenic layer is stimulated to differentiation and proliferation by small doses of viosterol following the initial impetus toward repair produced by the fracture

Cystic Nodules of Finger Joints—Nachlas has observed soft nodules on the terminal joints of the fingers that differ radically from the tophi in gout. The incidence of these nodules and their clinical course indicate that they are a pre-ossaceous stage of Heberden's nodes Studies of the contents of the nodules showed a gelatinous material high in calcium content The absence of uric acid and urates dissociates this condition from gout. In treating the nodules the discrete mass is frozen by an ethyl chloride spray A small transverse incision is made, and while the tissues are still hard pressure is applied on each side of the incision with the back of the knife and a clamp The contents of the sac pop out as a clear bead The area is wiped off and a sterile dry dressing is applied After a few days, the dressing is removed and the wound is found closed with little evidence of scar and without the original swelling When incision is not feasible, baking gives relief from pain and slight reduction in size.

Acute Intestinal Obstruction—McIver presents data on a third ten-year series of 156 cases (for 1918 to 1927) of acute intestinal obstruction of mechanical origin, excluding obstructions due to neoplasms or to strangulated external hernias The mortality in this series was 44 per cent, contrasting with 41 per cent in the years from 1908 to 1917 and 60 per cent in the period from 1898 to 1907 A detailed analysis of the mortality in the different types of obstruction is presented There are three salient factors that affect the mortality the lapse of time between the onset of the obstruction and the operation, the degree of interference with the circulation of the intestine and the age of the patient Pain and vomiting were recorded in all the cases, and distention was usually present Visible peristalsis was recorded in twenty-two instances (occurring chiefly in the early and the late postoperative obstructions), abdominal tenderness in sixty-one instances and muscle spasm in thirty-seven Elevation of the white count is suggestive of strangulation and the need of immediate operation A local anesthetic should be used in cases coming late to operation The figures showed a low mortality for ether anesthesia as contrasted with local, but this was interpreted on the basis of the fact that operation in the more desperate cases was done under local anesthesia Dehydration treatment by the administration of adequate volumes of physiologic solution of sodium chloride is extremely important During the last four years of the author's series he paid special attention to this phase of treatment, and although it was felt to be a life saving measure in certain cases, no lowering of the mortality rate was found as contrasted with that of other years He offers the explanation that while dehydration is usually an important factor in obstructions at any level, it is most striking in simple high obstructions Such cases are relatively infrequent. The obstructions are usually low and are often complicated by interference with the circulation of the intestine, a more important factor in determining the outcome than is dehydration

Chronic Endemic Ergotism—According to Kauntz, the etiology, symptomatology and pathology of ergotism are to a great extent simulated by thrombo-angitis obliterans Both ergotism and thrombo-angitis obliterans are practically limited to young and to middle aged male persons The Jews, who regard their ailments seriously, are more apt to seek medical advice, which explains why more cases of thrombo-angitis obliterans have been reported in this people The diet in both thrombo-angitis obliterans and ergotism includes to a great extent rye bread There is ample proof that this bread is frequently contaminated with ergot occasionally in toxic doses Greater precautions are advisable in cleaning and aging all the

grains susceptible to ergot infection, principally rye and wheat, particularly durum wheat The author produced pathologic effects suggestive of various vasomotor and trophic diseases by experimental ergotism in cocks Fresh and organized thrombi and organization of the thickened tunica intima were obtained In one of his more recent experiments, vessels were obtained with obliterating canalized thrombi, simulating thrombo-angitis obliterans Since small doses of ergot may be capable of aggravating the condition of a vessel already diseased, it might be found advisable for patients with thrombo-angitis obliterans to forego rye bread that has not been proved to be free from ergot Histamine and tyramine, commonly found in the human body and in ergot, should be carefully investigated as to their prolonged effect on the vessels, as they may be responsible for some of the vascular conditions under consideration

Pneumonia in Steel Industry—Brundage and Bloomfield state that reports from industrial sick benefit associations to the United States Public Health Service have consistently shown a higher incidence of pneumonia among employees of the iron and steel industry than in other industries as a whole. Occupational mortality statistics for England and Wales reveal an excessive death rate from pneumonia in certain occupations of Britain's steel industry Factors apart from working conditions, such as seasonal variation in the frequency of pneumonia, influenza epidemics, economic status of the workers, their age, nationality, extent of addiction to alcoholic stimulants, and prevalence of the disease in the community selected for study of the pneumonia problem were analyzed and found of insufficient influence to account for the high rate among the steel workers A study of working conditions in a large steel plant with especial reference to the occurrence of pneumonia showed that the disease was associated with exposure to heat hazards when subjection to wide changes in temperature was involved, also with outdoor exposure to storms and other inclement weather conditions, and with indoor exposure to humid, drafty conditions and wet clothing Sudden cooling or chilling of the body was indicated as an important predisposing factor Among the remedial measures suggested are 1. Mechanical devices to reduce the effective temperature in occupations involving exposure to radiant energy 2. Extension of the mechanization of processes involving heat hazards

These will doubtless tend to reduce the frequency and intensity of the workers' exposure 3 Adequate provision for change houses for employees exposed to the conditions that appear to predispose to respiratory diseases, and compulsory use of such houses Men perspiring freely after heavy work in front of the open furnaces were observed changing clothes while standing in a direct draft, others went home without changing their clothes even though they had become wet from perspiration 4 Shelters in stormy weather for those who work outdoors 5 Reduction of hours of work 6 Furtherance of health education of employees as to the danger of sudden chilling due to comparative inactivity following exposure to high temperatures, and the importance of suitable protective clothing 7 A visiting nursing service to instruct the patient and help arrange for medical and nursing care while pneumonia is still in its incipience

Neurogenic Vesical Dysfunction in Children—Smith and Engel consider the factors involved in cases of frank retention and incontinence, founded on a study of cases Their experience and a digest of the literature indicate that responsibility for either incontinence or retention can be placed in most instances on faulty innervation from the parasympathetics, which is generally associated with osseous fusional defects of the lower part of the spine, in which the nerve roots have become involved in associated fibrous tissue formation during the development of the individual In cases of retention, in this situation, degeneration of the parasympathetics apparently leaves the brakelike innervation from the sympathetics in control of the sphincters In cases of incontinence, which in their series comprised cases of primary incontinence and other cases, which, in the earlier stages, were undoubtedly cases of retention, they conclude that inherent muscle tonus of the sphincters, which is dependent on parasympathetic innervation, was absent from the first in the more aggravated cases and had been completely lost during the degenerative process wherein a primary retention had passed over into an incontinence Management is regarded as essentially surgical In cases of incontinence, reinforcement of sphincteric control should be attempted by muscle transplantation into the perineum encircling the urethra or by plastic tightening of the vesical sphincteric outlet In cases of retention, resection of the sympathetic chain releases the brakelike action on the sphincter, and good emptying power may be expected

 *Prevention of Colds D F Smiley, Ithaca —p 1420

Prevention of Colds—According to Smiley, there is at present no panacea for the prevention of colds Since epidemics of colds in student groups appear to be limited largely to the "cold-susceptible" 23 per cent, efforts directed at that particular group should be the most fruitful The interest of at least one seventh of these cold-susceptible students in the prevention of their colds can be aroused and sustained by offering "cold prevention" classes If, in these classes, matters of diet, alkalinization, ventilation, toning up of the skin vessels by ultraviolet rays or sunlight, and in special cases the correction of nose and throat abnormalities and the use of vaccines are stressed, an average reduction of approximately 46 per cent in the incidence of colds can be prophesied Which of these various factors is the most important is a question, but the ultraviolet or sunlight bathing is, undoubtedly, an essential factor in arousing and sustaining the interest of the patient in the project A definite advantage of this plan of attack is that it furnishes a means of applying a number of the principles that are now available for the prevention of colds

Scopolamine Amnesia in Labor—Macafee has used scopolamine in labor for the past year and a half He uses a modification of the method of van Hoosen, which consists in giving $\frac{1}{100}$ grain (0.00065 Gm) of scopolamine hydrobromide as soon as labor has definitely started, a second dose half an hour later and a third dose at the end of an hour All that is necessary to maintain the anesthesia for an indefinite period is to repeat the $\frac{1}{100}$ grain dose of scopolamine hydrobromide hypodermically every two hours He has varied the dosage from a single dose of $\frac{1}{400}$ grain of scopolamine hydrobromide to fifteen repeated doses In his thirty-three private cases, the results were exceptionally good in twenty-one cases, good in

six and fair in five. In his forty-seven hospital cases, the results were extremely good in twenty-five cases, good in thirteen and fair in nine. The advantages of the use of scopalamine are that it is easy to administer and, in a case that is seen early and properly treated, the patient passes through labor with the minimum of discomfort and wakes up after delivery in a much better condition than the ordinary patient.

Rare Abdominal Cyst—Chisholm reports the case of a woman, aged 49, who, on admission to the hospital, stated that she had had a lump across the stomach for several months. On examination, it suggested a large ovarian cyst, and the swelling could be felt through the vagina. The symptoms were not sufficiently urgent to make immediate operation necessary. When the abdomen was opened, the peritoneum of the anterior abdominal wall was found to be rather edematous, the pelvic organs, the appendix and the kidneys were found to be healthy. A cystic tumor, about the size of a large melon, was exposed. There were a few adhesions, none of them being intestinal. The tumor arose from the lower surface of the liver, the falciform ligament extending well down its anterior aspect. It was situated anteriorly, the lesser sac, stomach and gastro-hepatic omentum being behind it and free from it. The cyst arose from the inferior aspect of the liver, with which it was incorporated in front of the transverse fissure. The gallbladder showed round its right edge and had to be carefully dissected off. The tumor had a wide attachment above to the liver. The greater part of the tumor was removed, the cut edge being taken as near to the liver tissue as possible without actually entering it. The raw edges of the remainder of the base of the cyst were stitched over with catgut. The fluid that escaped from the cyst cavities was opaque but neither viscid nor blood stained. On the inner wall of one of the cystic cavities there was a dark stain, as if due to bile pigment. The fluid was not offensive or purulent. The gallbladder was not distended. The abdomen was closed in layers without drainage. When the patient was examined four months later, she was well and had no pain or tenderness. There was evidence neither of any recrudescence of the growth nor of free fluid in the abdominal cavity.

Puerperal Sepsis—Thomas classifies the lesions found in 800 cases of puerperal sepsis into four broad types of infection. In the first group the disease is limited to the lower parts of the genital tract; in the second there is evidence of an intra-uterine infection; in the third there is a spreading of pelvic inflammation involving the fallopian tubes, cellular tissue or peritoneum, and the fourth group includes all cases of blood infection without regard to the virulence or extent of the local lesion. There are degrees of severity within each group, but, on the whole, the gravity of the infection increases and the prognosis becomes more uncertain in the sequence given. A bacteriologic examination also shows that the frequency of streptococcal infections increases in the same order and that in the most serious type of the disease this organism is present in the blood or uterus in 75 per cent of the cases and is the determining factor in the ultimate issue. Local methods of treatment are restricted to the first two groups. Intra-uterine glycerin injections gave the most satisfactory and reliable response, whereas the oral administration of ergot and quinine was not followed by the good results claimed by certain authors. The amount of glycerin required varied with the degree of sepsis and with the stage of the puerperium, as much as 30 cc. being frequently necessary in recently delivered or grossly infected patients. The number of injections varied with the individual response. An analysis of the cases in the third and fourth group revealed the serious fact that in 70 per cent the streptococcus was the causal agent. The general treatment of these groups is similar to that of the first two groups though of a more intense character. In all cases, irrespective of grouping, the use of antiscarlatinal serum, in default of a specific serum for the streptococcus of puerperal sepsis, constitutes the only rational measure at present available. In the less severe infections of the earlier groups such a serum will have a prophylactic value, but the more serious infections demand its administration intravenously at the outset, on repeated occasions, and in a dosage to be determined by the nature of the response obtained. Metarsenobillon (a formaldehyde bisulphite derivative of arsphenamine) and vitamin A demonstrated conclusively that they do not possess any remedial properties that justify their administration.

Leukocytosis and Leukocytic Formula in the New Born J A Bauza —p 29
Prophylaxis of Congenital Syphilis E Lesne and A Linossier Ardoin —p 38

Hypotrophies of Early Infancy—Lereboullet and Baize conclude that the probable mode of action of insulin in the hypotrophies of early infancy consists in improving the carbohydrate metabolism and thereby the metabolism of fats and proteins, and permitting the fixation of large quantities of water in the tissues. This eutrophic action is clinically indisputable and is observed in about 80 per cent of the cases. It does not occur in athrepsia, but it is distinct in feeble infants (premature or not) whose weight curve remains static and in hypotrophic children in a state of denutrition before and after five months, whenever the cause of the nutritional disturbance is not linked to a well defined organic disturbance. The action of insulin seems to be less favorable in simple hypotrophies without emaciation, these appear to respond better to thyroid and thymic opotherapy. Daily doses of 1 unit of insulin per kilogram of weight seem to be sufficient and only exceptionally produce hypoglycemic accidents, which, moreover, are not serious. To prevent these accidents an additional amount of sugar should be administered in the diet. This is best done by adding from 20 to 30 Gm of sugar to the nursing bottle given fifteen minutes after an insulin injection, parenteral administration should be reserved for infants who vomit and for emergency in hypoglycemic accident. This excess of sugar also provides the infant with a supplementary ration, which insulin permits it to utilize. The insulin therapy is a temporary therapy and rarely needs to be continued more than three weeks.

"Catechin" in Therapy of Exophthalmic Goiter—Herzfeld and Frieder relate their experiences with thyroidal "catechin," a substance that Blum separated from the blood and that balances the action of the thyroid. The preparation of thyroidal catechin employed by the authors was in tablet form, each tablet containing 10 units. First they tried three tablets a day, but later they increased the dose to six and even nine tablets, and then gradually decreased it again. The improvement became noticeable as a rule during the second week of the treatment. The weight increased, the basal metabolism decreased, and sympathetic symptoms such as sweats and diarrhea disappeared quickly. The influence on the exophthalmos was likewise favorable, but the struma showed little change. The duration of the treatment varied according to the severity of the disturbance. As a rule, it had to be continued for from four to six weeks. The efficacy of the catechin preparation is largely dependent on certain dietary restrictions. During treatment the patients should abstain from meat, and stimulants in the form of coffee, tea, nicotine and alcohol should be avoided. The diet should supply large amounts of carbohydrates. Bread, foods prepared with flour, sweets, fruits and vegetables, and milk and milk products, particularly butter and cream, are recommended. Pure animal fats are permissible. The authors state that the treatment failed in only two of eighteen cases. One of these two patients did not follow the prescribed rules, and in the other one it was probable that a tumor existed in addition to the exophthalmic goiter. The disturbance was severe in all of the eighteen patients who were treated with catechin. Some of the patients had been under observation for several months.

and had proved refractory to other treatments. The authors state that studies are now under way to determine whether the thyroidal catechin influences the iodine content of the blood, as does insulin the sugar content of the blood of diabetic patients.

Symptoms and Roentgen Signs After Gastric Resection—Bremer and Held report a clinical and roentgenologic study of fifty-seven patients operated on for gastroduodenal ulcer in von Haberer's clinic in Cologne. There were two gastro-enterostomies and fifty-five partial gastric resections of Billroth I or Billroth II type. A satisfactory follow up study was possible in forty-eight cases. The striking feature was the absence of motor disturbances and of abnormal roentgenologic signs on the one hand, and the frequent subjective complaints on the other. After the Billroth I resection the stomachs emptied, as a rule, in from thirty to sixty minutes and after the Billroth II operation in from twenty to forty minutes. The roentgen studies of stomachs after the Billroth II revealed an enlargement of the mucous folds. The lumen of the efferent loop is widened and the mucous folds are widened and thickened. There were no pathologic signs. Peptic jejunal ulcer was not observed. The emptying was fairly rapid but not dumping. The stomach after the Billroth I operation, observed as early as twenty days after the operation, was noticeably diminished in size. The emptying of this stomach took place synchronously with the inspiratory act. Apparently the diaphragm exerted an effect on the diminished and distended stomach. The axis of the stomach, however, was not sufficiently perpendicular to cause dumping. Numerous roentgenologic observations demonstrated the changes that take place in this small stomach until, in the course of from five to ten months, it arrives at a permanent form. It becomes larger and its capacity increases. Stenosis of the stoma was not observed. Decided changes were noted in the topography of the mucosa of the first portion of the duodenum, the circular folds of Kerkring assuming a longitudinal arrangement. The emptying of the stomach is now rhythmic, is no longer influenced by the inspiratory act, and takes from one to one and a half hours. This specialized function seems to be conditioned by the anastomotic ring and the new bulb. The authors believe that in no other type of operation do the conditions approach the normal as closely as after the Billroth I. They point out that while von Haberer insisted that the patients adhere to a strict diet for at least one year and do not resume their occupations for from four to six months after the operation, these conditions are frequently not followed, because of unemployment and poverty among their patients. Of the forty-eight patients followed up, twenty observed no diet but remained in good health. Fourteen patients adhered to a diet and presented no subjective complaints. Ten patients were too poor to follow a diet. They did not gain in weight and complained of symptoms. In four patients who were out of work, lived on an insufficient diet and indulged in tobacco and alcoholic drinks, the results were bad. Three of these became symptom free after a dietetic treatment of from four to six weeks. The authors recommend that this type of patient be observed for a period of from one to two years with the view of obtaining for him proper nourishment and timely treatment of subjective complaints.

Calcium Carbonate Bile—Markus reports a case of a pure calcium carbonate stone. A roentgenogram taken with the patient in the erect posture revealed a large, dense shadow at the upper border of the right sacro-iliac joint. It was

shaped like a half moon and presented a fluid level. A smaller shadow was present about two vertebrae higher. With a film taken in the recumbent posture the shadow appeared oval and lay somewhat higher than before. At operation a mass was palpated in the gallbladder and a stone, the size of a cherry, in the cystic duct. The removed gallbladder, examined roentgenologically before it was opened, gave the same shadow. When opened, the gallbladder was seen to contain a pale green, thin bile suggestive of a beginning hydrops. The cystic duct contained a cholesterol stone with a whitish coating. The fundus of the gallbladder was occupied by a white, soft, oval mass, 4.5 by 2.5 cm. Chemical investigation of the gallbladder contents revealed that they consisted of 98.35 per cent calcium carbonate and 1.65 per cent organic matter in which traces of cholesterol were present. The case is reported because of the extreme rarity of calcium carbonate stones, there being about eight cases recorded in recent literature. No explanation for their genesis exists. Because the stone casts a dense shadow, denser than that of the gallbladder in a cholecystogram, and because a fluid level is formed, a roentgenologic diagnosis should be possible.

Leeches in Treatment of Thrombosis—Straaten states that the incidence of postoperative thrombosis did not diminish in von Haberer's clinic despite the recourse to calcium, thyroxine and the introduction of large amounts of fluids. In the last decade French surgeons successfully treated postoperative thrombosis of the lower extremities with the application of leeches. The author reports twelve cases of postoperative femoral thrombosis treated by the application of leeches. The patients were carefully observed and offer a basis for an opinion as to the value of the treatment. There was not a single mortality in the group. A considerable reduction in swelling was usually observed after from twenty-four to thirty-six hours. The author applied, as a rule, three leeches, repeating the treatment forty-eight hours later, if necessary. A study of the circulation in the vicinity of the application of the leech revealed definite alterations. The bleeding time was increased, as evidenced by transient oozing from the wound lasting from twelve to eighteen hours. The coagulation time was likewise prolonged by from three and a half to four minutes. The erythrocytes were diminished by 500,000 and the leukocytes increased by about 1,000. These changes were strictly local and were not observed in the general circulation. The prolongation of the bleeding time and of the coagulation time is the result of the well known effect of hirudin, a secretion of the buccal glands of the leech. The author concludes that leech therapy is the most effective means in the treatment of postoperative thrombosis. There is no evidence that it is capable of loosening the thrombus. The beneficial effect is the result of an improvement in the local circulation.

Massive Fluorosis of Bones and Ligaments—Møller and Gudjonsson's examination of seventy-eight workers engaged in crushing and preparing cryolite revealed silicosis of up to the second degree in thirty-nine. Three other occupational disorders also were noted. In thirty of the workers there was a peculiar sclerosing disease of bones and ligaments believed not to have been previously described in man and ascribed to deposit of calcium fluoride in the bones. Forty-two had from time to time a gastric disorder of acute onset and course, assumed to be the result of a slight cauterization of the gastric mucous membrane from transformation by the gastric hydrochloric acid of the ingested cryolite dust into hydrofluoric acid. In eleven cases there was a marked oligemia.

CALCIUM NEED AND CALCIUM UTILIZATION

ALICE R. BERNHEIM, M.D.
NEW YORK

In 1911, Sherman¹ called attention to the calcium deficiency of the average American dietary. Again, after twenty years, he² stated that "probably a larger proportion of the ordinary dietaries, both of adults and of children, can be improved by enrichment in calcium than in any other one chemical element."

It seems surprising, in view of the study and attention given in recent years to the subject of dietary needs, that such a calcium deficiency still exists. Yet, on further consideration, the reason for it may well be attributed to a prevailing opinion which holds that bread is "the staff of life" and the ordinary "mixed meal" represents a sufficient diet. This assurance is supported by Peters and Van Slyke³ in a recent publication, in which is found the statement that "under ordinary circumstances, of course, normal adults live in a state of calcium equilibrium, the daily loss being equal to the intake."

Information concerning calcium need, supply, utilization, and the forms in which it occurs in the body has been well presented by the work of Sherman, Orgler,⁴ Bergeim,⁵ Klinker,⁶ Aub⁷ and others. Enough data are available to show that, contrary to the general belief, the existence of optimum conditions in regard to calcium cannot be taken for granted but that special effort is necessary to assure adequate supply and utilization of this element.

CALCIUM REQUIREMENT

Sherman states that 0.45 Gm of calcium (0.63 Gm of calcium oxide) fills the actual daily requirement for adults, but this represents the minimum of actual need rather than the normal allowance. He considers that the normal, or "standard," allowance for protein, phosphorus and iron in the diet should be set 50 per cent above the average minimum, while for calcium the margin for safety should be even greater than this,

because of the uncertainties in regard to calcium absorption. He estimates the optimum allowance to be 0.70 Gm of calcium (1.0 Gm of calcium oxide), and his figures are widely accepted.

By a whole series of criteria, Sherman was able to show the beneficial influence of increased calcium (and vitamin G) through an additional amount of milk in the food mixture of families of rats thriving in the twenty-seventh generation on adequate uniform diet. He noted more rapid and efficient growth, lower death rates, and higher vitality at all ages, an increase of 10 per cent in the average longevity of adults, and greater extension of the prime of life, in that maturity was expedited and senility deferred in the same individual.

His conclusions are interesting. He says:

As there has been so strong a tendency to attribute longevity entirely to hereditary factors, it may be worth while to emphasize the fact that here in parallel groups of exactly the same heredity the influence of food on longevity is demonstrated with such degree of mathematical certainty as is represented by "chances" much better than 10,000 to 1, or with a hundredfold greater certainty than is usually considered necessary for the conclusive establishment of such scientific observations.

He believes that a number of weaknesses and increased susceptibilities to infection may be the results of calcium deficiency. He holds that the difference between a merely average and a better-than-average nutritional condition has a real significance for the maintenance of health or for recovery from disease.

Unfortunately, it is not so easy to conduct such clear-cut experiments on the human subject as those performed by Sherman on rats.

Inquiry into the dietary histories of more than 4,000 patients (unselected cases) in the New York Hospital revealed only two whose diets were adequate in calcium, and both of these were in the hospital because of injuries through accident and not because of disease.

If the same number of apparently healthy persons should be thus questioned, a very similar calcium deficiency might well be disclosed. But who can say that in these apparently normal people general health and longevity have attained their optimum biologic possibilities? Obviously, too many ailments occur in middle life, and people die too young.

Persons differ markedly in their adaptabilities. Some may respond to insufficient supply of essential elements in terms of frank disease, depending on their points of least resistance, others may maintain themselves in the manner of Sherman's rats, before the addition of milk to their diet—seemingly normal, but really considerably below their potentialities for full health and long life.

A large supply of calcium is present in the bones, and this store can be drawn on over a considerable period of time to substitute for a dietary lack without pro-

ducing obvious osteoporosis or a reduced calcium content of the blood. It is, however, entirely possible that the calcium depletion of the bones in old age, which is considered a normal manifestation, may be but the result of a prolonged insufficiency in the calcium intake.

Like Sherman's results with rats, it has been my experience with normal persons that a sustaining diet enriched by the addition of calcium and vitamins makes for the difference between "passable" and "buoyant" health. And, furthermore, the marked improvement seen with the use of a high calcium regimen in the treatment of a number of apparently unrelated disorders corroborates Sherman's opinion of the advantages of an adequate calcium diet in the recovery from disease.

From the study of these cases, the importance of calcium in human nutrition and health seems far greater than is now commonly realized. Reports of this investigation will be given in another communication. The purpose at present is to consider how the adequate supply and utilization of calcium may be attained, accepting 0.70 Gm. as the optimum daily requirement. To this end three main considerations are essential:

- 1 Its sources of supply
- 2 The proper preparation of food in order to conserve the calcium content
- 3 The factors that govern its absorption

CALCIUM SUPPLY

Sources of calcium supply are food, water and calcium salts, as such. Meats and fish are known to be poor in calcium content, but the portions of fruits, vegetables and dairy products included in the ordinary diet are thought to be adequate sources of supply.

TABLE 1—Foods with Their Calcium Equivalents*

Milk	1.5 pounds (3.4 glasses)	} Good sources of calcium
Cheese	0.25 pound	
Apples	20.2 pounds (50 large apples)	} Erroneously considered good sources of calcium
Beans (string)	3.2 pounds	
Beets	0.4 pounds	
Bread (white)	7.3 pounds	
Bread (brown)	5.5 pounds	
Butter	11.0 pounds	
Cabbage	3.9 pounds	
Carrots	3.7 pounds	
Cauliflower	1.5 pounds	
Celery	2.7 pounds	
Corn (green)	27.5 pounds	
Eggs	2.6 (20 eggs)	
Grapefruit	7.3 pounds	
Grapes	12.0 pounds	
Lentils	1.8 pounds	
Oatmeal	2.3 pounds	
Oranges	4.9 pounds	
Pears	12.9 pounds	
Peas (green)	9.9 pounds	
Potatoes	17.0 pounds	
Rice	17.6 pounds	
Tomatoes	11.0 pounds	
Watermelon	26.4 pounds	
Meat (lean beef)	26.4 pounds	} Poor sources of calcium
Fish	14.7 pounds	
Water (Catskill and Croton)	190 quarts	

* Figures calculated from Sherman's tables

It is of interest to examine some of these supposedly calcium rich substances to see what amounts will furnish the calcium requirement. Table 1 gives a list of some of the common foods, the quantity of each, as indicated, containing the calcium requirement for one day 0.70 Gm. of calcium (1.0 Gm. of calcium oxide).

It is obvious that unless milk or cheese is included in the diet it would be exceedingly difficult to fill the calcium need, since inordinately large amounts of other foods and water would have to be ingested, quantities far beyond the capacity of the normal individual. Thus,

for example, if the needed calcium were to be obtained from white bread alone, it would be necessary to eat more than seven loaves, if from potatoes, seventeen pounds, if from butter (a dairy product), eleven pounds, and if from apples, fifty large ones. Whereas, about one quart of milk or one-fourth pound of cheese will supply the necessary calcium.

LOSS OF CALCIUM (AND OTHER SALTS)
IN COOKING

The poor supply of calcium furnished by vegetables and fruits is made still more meager through the method of cooking in common use. Vegetables are, for the

TABLE 2—Essential Factors in Calcium Metabolism

Intake	
Food	
Water	
Calcium salts (as such)	
Absorption	Through the intestines, regulated by
1 pH within the intestine	salts are absorbed in proportion to their relative solubilities
Acid pH 3.0-6.9	calcium salts are soluble in acid solutions
Neutral pH 7.0	
Alkaline pH 7.8-9.8	Intestinal, pancreatic, biliary secretions
calcium salts	are insoluble in alkaline solutions
2 Other substances in the diet	
(a) Excessive fats	calcium soaps of fatty acids are not absorbed
(b) Excess of phosphates	tertiary calcium phosphate is insoluble
(c) Oxalic acid (in leafy vegetables)	calcium oxalate is insoluble
(d) Lactose in fairly large amounts	promotes absorption
Blood

Feces	600 mg.
Urine	190 mg.
Negative balance	490 mg.

most part, cooked in large quantities of water. Considerable amounts of the calcium and other salts are retained in the water, which is usually discarded. In restaurants, in America, the water containing the salts is frequently added to soups, but it is lost so far as the vegetables are concerned. Answers to questions addressed to a large number of housewives and cooks, over a period of more than five years, concerning their methods of preparing vegetables, show that only about 1 per cent of them use the water in which the vegetables are cooked. Sherman and Hawley⁸ and McClugage and Mendel⁹ showed that calcium is better absorbed from milk than from vegetables, another factor which makes vegetables a poor source of calcium supply.

In spite of widespread attention given to dietary needs in newspapers, magazines and health centers, the vast majority of people in America still cook the way they have always cooked. Physicians all too infrequently concern themselves with dietary requirements.

Undoubtedly, much could be done to insure the utilization of the mineral content of food, if advice concerning its preparation came directly from the physician

Table 2 gives an outline of the essential factors in calcium metabolism

CALCIUM ABSORPTION

Calcium is absorbed through the small intestine and the degree of absorption is governed by two main factors (1) the hydrogen ion concentration within the intestine, (2) the relative proportion of other substances in the diet. Some investigators are of the opinion that vitamin D exerts an influence on the absorption of calcium. This matter, however, is not yet settled, since recent work tends to show that its effect is not so much on absorption as on the intermediary metabolism of calcium.

Hydrogen Ion Concentration—Solubility is essential for absorption. Insoluble calcium salts are formed in an alkaline medium and are thus not absorbable, whereas in an acid medium they are soluble and can be absorbed. Measures that promote intra-intestinal acidity favor the absorption of calcium.

Substances in the Diet Affecting Absorption—An excess of fats in the diet interferes with the absorption of calcium, fatty acids combine with calcium, forming insoluble soaps which cannot be absorbed. An excessive amount of phosphorus in proportion to calcium also inhibits absorption, a condition due, in all likelihood, to the formation of the insoluble tertiary calcium phosphate from which calcium is unavailable. Oxalic acid (present in leafy vegetables) combines with calcium, forming insoluble calcium oxalate, which cannot be absorbed.

Bergeim showed that absorption of both calcium and phosphorus is markedly increased by the addition of lactose to the diet. This result he attributes to the increased acidity due to lactic acid fermentation in the intestine. Other carbohydrates do not have this effect. Large quantities of sucrose favor absorption to a small extent, but maltose and starch actually decrease the absorption of both calcium and phosphorus. Mellanby¹⁰ states that cereals—bread, oatmeal, maize, rice—hinder the calcification of bone.

Bergeim also showed that cod liver oil aids the absorption of calcium and phosphorus, and thus suggests that vitamin D does exert some effect on this phase of calcium metabolism.

Kahn and Roe¹¹ have shown that calcium may be adequately absorbed from its various salts if they are taken in the interdigestive periods when the intestinal reaction is least alkaline. The failure of much oral therapy is due, undoubtedly, to the administration of calcium at times (usually after meals) when intestinal alkalinity is highest, and it is absorbed insufficiently or not at all.

In the light of these factors which govern the absorption of calcium it is likely that individual differences in the degree of absorption exist. Variability in the incidence of intestinal alkalinity among normal persons is probably as frequent as the occurrence of different degrees of gastric acidity. There is convincing clinical evidence that in at least one abnormal condition, that of hypersensitiveness, calcium is poorly absorbed, apparently because of a too high intestinal alkalinity,

since with the production of intra-intestinal acidity absorption becomes adequate.¹²

BLOOD CALCIUM

Klinke has shown that calcium exists in the blood in three forms: the nondiffusible, bound to protein, and the diffusible, of which there are two forms, the ionic and the complex ionic. The ionic is said to be the available calcium, but actually little is known concerning the utilization of these three forms.

The finding of a normal figure for the total blood calcium is commonly considered an indication of a normal calcium condition. This, however, is not always so, since imbalances among the three forms may occur even if the total amount is within the normal range. A total blood calcium (in the fasting state) below or above normal, on the other hand, is usually an indication of an abnormal calcium state.

The parathyroid glands and vitamin D are necessary for preserving the normal balance among these three forms, as are also the normal amount of protein and phosphorus in the blood and the proper hydrogen ion concentration. This situation is not a simple one and obviously entails a number of coordinations and interrelationships. In the light of our present knowledge, so far as the normal individual is concerned, it would seem that the adequate supply of protein, calcium, phosphorus and vitamin D will assure the proper balance. In diseases of the parathyroid glands, or in conditions in which the protein content of the blood is increased or reduced in amount, in acidosis or alkalosis, special measures directed toward the control of the disorders must be employed.

HIGH CALCIUM, HIGH VITAMIN DIET

An adequate calcium schedule is one which not only contains the necessary amount of calcium but also those factors which make for the proper utilization of calcium.

The term "high calcium, high vitamin" is used to describe a diet in which all the food essentials are included but in which calcium and vitamins are especially stressed.

It is interesting to note that the various dietary regimens used in the treatment of tuberculosis, and devised especially to supply sufficient calcium, are exceptionally inadequate, largely because the absorption of calcium is rendered insufficient by too frequent feedings and by the food combinations commonly used.

By "high calcium" is meant from 0.70 to 1.0 Gm of calcium, which may be obtained from one quart of milk, or from one-fourth pound of cheese. If, for any reason, these foods cannot be taken, this amount may be obtained from 80 grains (5 Gm) of calcium lactate or 160 grains (10 Gm) of calcium gluconate a day. By "high vitamin" is meant some form of vitamin D (the equivalent of 30 drops of viosterol) in addition to from 6 to 8 ounces (180 to 240 cc) of orange juice and from 6 to 8 ounces of tomato juice. If calcium salts are substituted for milk or cheese, the vitamin A supplied by the latter is lost, and to make up for this deficiency cod liver oil, or a cod liver oil concentrate (which contains both vitamins A and D), is employed in place of viosterol.

Orange and tomato juices are used in the diet because of their content of vitamins A, B and C, and of citric acid. Sherman says, "probably each of the vitamins A, C and D bears an important relation to the metab-

¹² Unpublished data.

olism of calcium and phosphorus in the development of bones and teeth." The mechanism of their action awaits further investigation. Vitamin B plays a rôle in the maintenance of intestinal tonicity¹³ and in this effect probably has a bearing on the absorption of calcium as well as of other substances. Citric acid affects the diffusibility of calcium in the blood and plays an important part in certain diseases of the blood vascular system.¹²

It is exceedingly unusual to find an intolerance to orange or tomato juice. They are taken without difficulty even in cases of peptic ulcer. In fact, results in some of the disorders of the digestive tract—constipa-

TABLE 3—Schedule for the High Calcium, High Vitamin Diet

Breakfast	
Orange juice, 6 to 8 ounces	
Another fruit (except bananas), cooked or raw (if desired)	
Two glasses of milk (or clabber, or buttermilk)	
Coffee, if desired	
Luncheon	
Vegetables cooked or raw (except potatoes)	
Salad (with lemon dressing and without oil)	
Fruit, cooked or raw (except bananas)	
Two glasses of milk (or clabber, or buttermilk)	
One or two hard boiled eggs (if desired)	
Dinner	
Tomato juice, 6 to 8 ounces	
Meat or fish	
Anything else desired	
Ordinary portions to be taken, and no second helpings if weight reduction is desired	
Eight teaspoonfuls of lactose a day. The lactose may be taken at any time but it is suggested that it be taken in the milk, 2 teaspoonfuls to each glass.	
Some form of vitamin D 30 drops of viosterol, or its equivalent	

tion, duodenal ulcer and colitis—are among the most satisfactory obtained from the use of the high calcium, high vitamin diet.

Ordinarily, vitamin D is supplied by the action of the sun on the skin, and only small and inadequate amounts are found in food. The question of the desirability of having vitamin D every day throughout the whole year is still unsettled. Until further knowledge concerning the storage and utilization of this substance in the body is acquired, a plan is suggested, based on the fact that nature provides both sunny and rainy days. Ordinarily, during the summer months, if exposure to the sun is possible and a good coat of tan can be obtained, no other means of administering vitamin D is prescribed. Individuals who do not tan apparently do not manufacture their own vitamin D very adequately. Fair-skinned persons who do not tan may therefore take vitamin D by mouth four days a week the year round, thus getting four sunny and three rainy days a week. What relationship there is between pigmentation of the skin and activation of the sterol of the skin by the actinic rays to produce vitamin D is undetermined. In respect to this relationship it is an interesting phenomenon that three individuals, after taking viosterol for several months, tanned in the sun for the first time in their lives.

Bread and other starches, butter and oil are omitted from the two high calcium meals (breakfast and luncheon) because, without starch and additional fat, conditions are more favorable for the absorption of calcium.

Calcium and vitamins may, of course, be acquired by other dietary arrangements, but this schedule is designed to promote the maximum absorption of calcium from

the diet. In America it is the common practice to strive for as much variety in foods as possible, on the ground that people tire of eating the same foods every day and so lose their appetites. This attitude is, evidently, largely artificial, and it is of considerable interest to see an initial opposition to the sameness of the two meals (breakfast and luncheon) give way not only to willing acceptance but to complete enjoyment of the regimen. It is extremely rare to hear complaints of monotony.

The long-lived Bulgarians of Metchnikoff fame were thought to owe their longevity to *Bacillus acidophilus*, which, in prevailing over the putrefactive organisms in the intestine, saved the individual from absorbing toxins. May not this longevity be due rather to their diet, largely composed of sour milk and sour cabbage, thus providing sufficient calcium and the optimum acid medium for calcium absorption?

Cantarow,¹⁴ in a recent report on calcium therapy, considers the pharmacologic effects and the use of calcium salts, vitamin D and parathyroid extract in tetany, disturbances of ossification, pregnancy and lactation, eclampsia, acute hepatic insufficiency, jaundice, hemorrhage, edema, atopy, lead poisoning, tuberculosis, ulcerative and mucous colitis, and a number of other conditions. The fundamental importance of calcium to cell life accounts for its wide usefulness. Calcium medication is undoubtedly of value in a number of diseases. Its effectiveness has been greatly increased through the investigations of Kahn and Roe (who showed how calcium, by the oral route, is best absorbed), through Collip's parathyroid extract, and through the production of calcium gluconate, which makes possible the intramuscular administration of calcium.

Scant attention, however, has been given to calcium therapy by means of diet, a method that yields surprisingly satisfactory results.

SUMMARY

- 1 The average American dietary is poor in calcium content.
- 2 The calcium requirement is 0.70 Gm of calcium (1.0 Gm of calcium oxide) a day.
- 3 General health is improved and recovery from disease aided when the optimum calcium supply and utilization are assured.
- 4 Without milk or cheese in the diet it is difficult to obtain the needed calcium through food alone.
- 5 Utilization of calcium is ineffectual, even with a sufficient calcium intake, unless the factors that control the absorption of calcium are also adequate.

Osteitis Fibrosa Cystica—Hyperparathyroidism or generalized osteitis fibrosa cystica is a clearcut, distinct disease entity caused by an increased secretion of the parathyroid hormone. This disease was first recognized clinically by Mandl in Vienna and by Du Bois in America. All cases thus far reported have been due to a parathyroid adenoma. The fact that it is a disease of endocrine origin implies that the entire skeleton is affected. Arthritis and Paget's disease are never generalized skeletal diseases. This fact alone argues against their being of parathyroid origin. Hyperparathyroidism is a disease characterized by definite alterations in the calcium and phosphorus metabolism as well as by certain symptoms and signs—Bauer, Walter. Hyperparathyroidism. A Distinct Disease Entity, *J Bone & Joint Surg* 15 135 (Jan) 1933.

DEHYDRATION IN EPILEPSY

J L FETTERMAN, MD

AND

H J KUMIN, MD

CLEVELAND

The pioneer work in the clinical application of restricted fluid intake to the treatment of epilepsy was done by Temple Fay,¹ although Hartenberg² claimed earlier use of this method as far back as 1913.

This treatment was based on the finding of increased collections of cerebrospinal fluid in epileptic patients, demonstrated by surgeons,³ by pathologists, and by roentgenologists using encephalography. Further basis for this method of treatment had been found in experimental work showing that excessive fluid predisposes animals to convulsions. Also, Gamble⁴ showed that there was a tendency to retention of body fluids just before a seizure, and McQuarrie⁵ demonstrated a parallelism between hydration and increased seizures.

Fay's⁶ detailed observation on the therapeutic effect of dehydration in twenty-three cases of epilepsy appeared in 1931. His results showed a definite improvement in about 60 per cent of the cases.

Further favorable results from a combination of dehydration with a ketogenic diet were reported by Palmer⁷ in one case and by Abbott and Fresk⁸ in twelve cases. Likewise, there has been a surgical application of Fay's "mechanical theory of epilepsy" by Swift,⁹ who has developed an operative procedure to relieve venous obstruction by "mobilization of the transverse sinus."

This conception of the nature of epilepsy has been questioned by Pagniez¹⁰ and challenged by Cobb¹¹. Cobb agrees with the observation of abnormal accumulations of cerebrospinal fluid in the arachnoid space but asserts that the pressure must be higher in the ventricles than in the arachnoid space about the cisterna magna, and lowest of all in the region of absorption over the ventricles. Fremont-Smith,¹² by accurate pressure measurements, demonstrated little difference during periods of dehydration as compared to periods of forced hydration.

On the clinical side, Cameron¹³ found dehydration of little value in the treatment of twelve institutional epileptic patients. Doolittle¹⁴ reported only eight of twenty-four epileptic patients improved on a regimen combining ketogenic diet and water restriction.

In view of the conflicting opinions on this subject, we shall report our clinical experience with the dehydration treatment of twenty-one epileptic patients. We realize that a report on therapy in epilepsy must take into account the type of patient, the duration of the illness and especially the factor of time. In consequence, the evidence gained from a brief study of so few cases over a short space of time in a disease so intangible as epilepsy can carry little weight.

NATURE OF STUDY

Our twenty-one subjects were taken from a larger group of some 100 epileptic patients who attended an outpatient epileptic clinic. There were two criteria used in the selection of patients: 1 The attacks should be of a type and frequency that could be tabulated. 2 The patients should be able to cooperate.

The majority of our patients belonged to the idiopathic epileptic group, four had organic brain lesions, one case was diagnosed hystero-epilepsy. Most of our patients had been under our own observation for a period of from one to ten years, the course of the disease being well known in each instance. A routine Binet mental test, rechecked at intervals, showed an average intelligence quotient of 75.

PROCEDURE

Nine patients were hospitalized, each for a period of about a month. The daily free fluid intake was started at 1,000 cc., and reduced by 100 cc each day or on alternate days, until the patient was allowed to have but 400 to 500 cc. This level was maintained for from one to two weeks, then the patient was allowed all the fluids he could take—from 4 to 7 liters in twenty-four hours. A comparison was made between the frequency of attacks during the periods of dehydration and of hydration.

Twelve ambulatory patients, excluding those who had been hospitalized, were placed on a similar dehydration program. They were advised, after a gradual reduction, to limit their free fluids to 500 cc daily. In addition, most of them were put on a diet with a predominant acid ash. The subjects who had been taking phenobarbital were allowed to continue with such medication, lest the discontinuance of sedative therapy precipitate status epilepticus. (One of the first "dehydration" patients, not included in this study, died in status.)

This regimen was maintained from three to twenty-two months. The cooperation was checked frequently by the simple expedient of measuring the specific gravity of the urine. A low specific gravity was a clear indication that the diet was not strictly followed.

Unfortunately, perfect cooperation was not secured in all instances. The adherence of the average epileptic patient to a strict regimen is subject to lapses. Even in hospitalized cases, it is sometimes difficult to combat thirst.

RESULTS OF TREATMENT

The results of the dehydration treatment are summarized in the accompanying tables. Table 1 gives the details of the hospitalized patients. Table 2 is a condensed outline of the data from the ambulatory patients.

The nine hospitalized patients presented cases of chronic epilepsy, most of them had been having frequent seizures over a period of years. The course of their illness had been little influenced by earlier therapy. A brief trial of dehydration made little change in their status. It is noteworthy that a change in the regimen from dehydration to hydration induced seizures in one

subject but did not precipitate attacks in the others. Also, the withdrawal of phenobarbital from those on a dehydration program induced attacks regularly.

There was no striking change in the general health of the patients during dehydration. All complained of thirst—a few, quite bitterly. The others became readily accustomed to the low intake. As has been noted by other observers, the specific gravity of the urine rose. Acetone appeared occasionally.

years. Earlier therapy had not benefited them substantially.

During the period of dehydration, there was no marked alteration in the general health or in the frequency of the seizures. E. G., a girl, aged 15 years, whose epilepsy developed after an attack of encephalitis, responded well to the treatment with phenobarbital and dehydration. The attacks stopped for eighteen months. When the dehydration was discontinued, there were no

TABLE 1—Hospitalized Patients

Number	Patient	Age, Years	Duration of Disease	Type	Previous Status	Status During Dehydration	Effect of Hydration	Comment
1	M S	35	24 yrs	Idiopathic	Phenobarbital and sodium borate, 1 grand mal attack per month	500 cc. for 2 weeks, no attack "uncomfortable from thirst"	7 liters in 24 hours, 2 attacks	Further dehydration ambulatory, no change
2	M C	17	16 yrs	Idiopathic	Frequent attacks little influenced by therapy	500-200 cc., one grand mal attack in 2 weeks	5 liters in 24 hours, no attacks induced	Dehydration, ambulatory, slightly better
3	S B	23	12 yrs	Idiopathic	Frequent attacks, little influenced by therapy	1,000 cc. for 10 days, 500 cc. for 10 days, phenobarbital stopped, grand mal attacks	5 liters plus phenobarbital, no attacks	Dehydration ambulatory, no benefit
4	I Z	18	11 yrs	Idiopathic	1 grand mal attack per week	600 cc. for 4 weeks, grand mal per week	4.5 liters, no change	Went to epilepsy colony
5	T Z	18	7 yrs	Idiopathic	Grand mal per week on phenobarbital	2 weeks 600 cc., same	Moderate hydration, no change	Dehydration, ambulatory, no change
6	S K	13	1 yr	Idiopathic?	Occasional petit mal attacks	400 cc. for 4 weeks, unchanged	No hydration	No follow up
7	A C	45	33 yrs	Idiopathic	Frequent (grand mal per week) attacks on phenobarbital	600 cc. for 2 weeks, no change	No change	Short psychotic episode
8	S B	32	23 yrs	Idiopathic	1 grand mal attack per week	400 cc. for 2 weeks, no change, spinal fluid pressure	Unchanged, same during hydration and dehydration	Dehydration not followed
9	B B	20	17 yrs	Organic	Frequent grand mal attacks	600 cc. for 2-3 weeks, no change, phenobarbital stopped, grand mal attack	Hydration of 6 liters plus ampoules of pitressin, no attacks	Dehydration not continued

TABLE 2—Ambulatory Patients

Number	Patient	Age, Years	Duration of Disease	Type of Epilepsy	Previous Status	Period of Dehydration	Average Seizures		Comment
							Before	After	
1	V V	13	7 years	Idiopathic	Attacks unchanged by sedatives, ketogenic diet, etc.	10 months	15	14	No change
2	A T	19	18 years	Idiopathic	Phenobarbital, no effect	8 months	23	23	Course unchanged
3	P M	40	3 years seizures also from 1892-1902	Organic (?) arterio-sclerosis	Phenobarbital, pellagra diet, no change	7 months	5	6	Attacks continued
4	E G	16	15 years	Organic (?) encephalitis in infancy	No previous study	18 months	23	0	Attack free during dehydration plus phenobarbital
5	A B	22	9 years	Organic (?) encephalitis at 2 years	Improved by phenobarbital	14 months	1	23	No improvement
6	S D	41	4 years	Idiopathic	Slight improvement by phenobarbital	8 months	14	13	No change
7	W M	28	19 years	Idiopathic	Slight improvement by phenobarbital	14 months	1	1	No change
8	P C	41	7 years	Idiopathic	Improved by phenobarbital	8 months	0.1	0.1	No change
9	F G	40	9 years	Organic (?) chronic alcoholism	Little response to therapy	22 months	58	37	No remarkable change
10	L W	41	15 years	Idiopathic	Some improvement under sedatives	9 months	14	0.3	Practically no change
11	E C	30	20 years	Idiopathic	Slight improvement with sedatives	3 months	12	12	No change
12	S G	32	20 years	Idiopathic	Sedative, ketogenic diet, little improvement	24 months	12	12	No change

Four of the nine patients continued on a regimen of dehydration following the hospital stay. M. S. showed no change in the number or severity of attacks for a period of six months. B. B. likewise was not benefited by the low fluid intake. M. C. was decidedly relieved for three months, only to suffer a return to her usual periodicity of seizures. T. Z. was improved during dehydration, but there was further reduction in attacks when unlimited fluids were allowed.

The twelve patients included in the ambulatory group were likewise chronic epileptic subjects whose seizures were frequent and had been present for a period of attacks, but when the phenobarbital was discontinued, the attacks returned. The benefit that this patient enjoyed was therefore to be attributed more to the sedative therapy than to the dehydration.

COMMENT

In general, we felt that the influence of dehydration was not significant. There were no clear-cut instances of marked improvement. The hospitalized patients had almost as many seizures during strict fluid limitation as during a copious fluid intake. Patients who had been 'free' of attacks on phenobarbital and dehydration

developed spells when phenobarbital was omitted but did not develop seizures when fluid was allowed.

Our negative results, consistent with Cobb's interpretation, are out of harmony with the favorable reports of Fay and others. For this difference there are several possible explanations. Our patients had chronic epilepsy and their illness could be little altered by any therapy. The same explanation might be offered for the negative results reported by Cameron for institutional cases. Secondly, our patients may not have cooperated perfectly. It is doubtful, however, whether patients can follow a strict regimen of dehydration when all other medical teaching is to "drink all the water you can." Lastly, the preliminary encephalography performed by Fay for his patients induced a reaction which reaches far beyond the mechanical influence of fluid withdrawal. Grant¹⁵ reports an increased cell count after encephalography. Two of our patients not listed in this series because dehydration was not instituted remained free of attacks for long periods after encephalography alone.

SUMMARY

Our results were essentially negative, a program of dehydration had little influence on the course of the epilepsy. The change to hydration did not, with any regularity, precipitate attacks. The results of other changes in treatment, such as withdrawal of phenobarbital, emphasized the relatively minor role played by fluid intake.

TREATMENT OF LOCALIZED STAPHYLOCOCCIC INFECTIONS WITH STAPHYLOCOCCUS TOXOID

C. E. DOLMAN, MB, MRCP, DPH (LOND)
Research Assistant and Clinical Associate, Connaught Laboratories,
University of Toronto
TORONTO

In 1928 an immunologic disaster occurred at Bundaberg, Queensland, which resulted in the death, within twenty-four hours, of twelve children out of twenty-one injected with diphtheria toxin-antitoxin mixture, subsequently proved to be contaminated with *Staphylococcus*. Since the publication of the report of the royal commission¹ appointed to inquire into these fatalities, there has been a noteworthy revival of interest in the toxigenic properties of the *staphylococcus*. It would be out of place here either to offer an historical survey of published work on *staphylococcus* filtrates or even to discuss in detail the various properties that have been attributed to them. But mention should be made of the work of Burnet,² which has received confirmation and amplification from many quarters, establishing the fact that under appropriate environmental conditions certain strains of *staphylococci* will produce a true exotoxin.

STAPHYLOCOCCUS EXOTOXIN

The effects of this toxin on the cells and tissues of the rabbit are specific and highly destructive. Erythrocytes, for instance, are hemolyzed and leukocytes disintegrated, while necrosis of epidermal, subcutaneous or

muscular tissues results from injection into them of relatively small amounts of *staphylococcus* toxin. Further, if a sufficient quantity of *staphylococcus* toxin is injected directly into its blood stream, a normal rabbit will die with characteristic signs and remarkable rapidity. These effects are reproducible on the cells and tissues of other laboratory animals. For instance, the erythrocytes of the sheep, cow, monkey, rat, guinea-pig, cat, horse and man are to varying degrees susceptible to lysis by *staphylococcus* toxin, although rabbit erythrocytes are much more susceptible than those of the other animals tested, and for some reason, so far unexplained, the rabbit alone among these animals has erythrocytes against which the hemolytic power of a *staphylococcus* filtrate serves as a quantitative measure of its true toxin content. Again, the skin of the guinea-pig, though less sensitive than that of the rabbit, can also be used for the quantitative assay of *staphylococcus* toxin through its dermonecrotic power, and Parish and Clark³ have recently published their reasons for preferring the guinea-pig for this purpose. I have noted also that subcutaneous injection of the toxin will lead to local necrosis, not only in the rabbit but also in the guinea-pig, mouse and horse.

The rapid death of rabbits given an intravenous injection of a *staphylococcus* filtrate was reported twenty-five years ago by Kraus and Pribram,⁴ and their observation has been confirmed by various subsequent writers. Within the past year or so Gross,⁵ Parish and Clark,³ and I⁶ have independently noted that guinea-pigs and mice were susceptible to the rapid lethal effect of *staphylococcus* toxin. Further, I have found that the cat and the rat will also die within a few minutes, and have already reported the death of a horse within two hours, after intravenous injection of *staphylococcus* toxin. The pathologic changes found in the tissues of animals killed in this way are very characteristic and will shortly be described in a separate publication.

A fairly close acquaintanceship with these properties of *staphylococcus* toxin and a study of the toxigenic capacity of strains isolated from human patients led me to suppose that many of the pathologic changes in localized staphylococcic infection might be attributable to the exotoxin. If this supposition was correct, and a suitable antigen was available, it appeared possible that active immunization of human patients against staphylo-toxin might result in a favorable modification, and perhaps cure, of their present staphylococcic infections, with some degree of protection against similar infections in the future.

STAPHYLOCOCCUS TOXOID

The fact that *staphylococcus* toxin could be detoxicated by the addition of solution of formaldehyde and yet remain antigenic (a procedure to which Ramon's work on diphtheria toxin had drawn renewed attention a few years previously) was apparently first recorded by Burnet² in 1929. More recently, Burnet⁷ has discussed in three papers the optimum conditions for preparing the toxoid, and also its flocculating properties and binding power against animal antitoxic sera. Panton, Valentine and Dix,⁸ and I⁶ have also

noted the possibility of detoxicating staphylococcus toxin with solution of formaldehyde. Before attempting to immunize human beings therewith, I used toxins treated with formaldehyde ("toxoids"), obtained from highly toxigenic staphylococcus strains, as antigens for rapidly inducing a marked degree of active immunity in the rabbit and horse, against the hemolytic, dermonecrotic and lethal properties of the toxin. The serum of animals immunized in this manner neutralized and gave passive protection against the same properties of toxin prepared from any strain.

A group of six normal male laboratory workers then volunteered to receive increasing doses of staphylococcus toxoid at weekly intervals by subcutaneous injection. An increase in the serum content of staphylococcus antitoxin was in each case measurable at the end of the course of injections. The actual increment varied within wide limits in the different cases. The reactions also varied with the different individuals, from the slightest local tenderness to a painful, red, swollen arm, with mild general malaise on the day following the injection. In no instance was the reaction of such magnitude as to preclude the advisability of giving small subcutaneous injections of the toxoid to human patients suffering from localized staphylococcic infections.

The samples of toxoid used in this work were prepared by adding 0.3 per cent solution of formaldehyde (U S P) to the pooled toxins obtained from several highly toxigenic strains, recently isolated from staphylococcic lesions of various types in human patients. The toxins were obtained by means of a modification of Burnet's method, which I⁹ have fully described elsewhere. After the toxin treated with formaldehyde had been incubated at 37 C for forty-eight hours, samples were taken out and tested at intervals for residual toxicity. The toxoid had to pass very stringent tests before being released for use on human patients. For example, a representative pooled toxin is one of which originally 0.0003 cc sufficed completely to hemolyze 1 cc of a 1 per cent suspension of rabbit erythrocytes in physiologic solution of sodium chloride after one hour's incubation in the water bath at 37 C, of which 0.00014 cc when injected intradermally into the back of a closely clipped rabbit would induce an area of necrosis having a diameter not less than 0.5 cm, and of which 0.1 cc injected intravenously in a rabbit weighing 1 Kg would cause death of the animal within one hour. Such a toxin would not be considered sufficiently detoxicated until 0.1 cc would induce neither hemolysis nor skin necrosis with the aforementioned standard conditions, or until 3 cc could be injected intravenously into a normal rabbit's veins without causing any apparent symptoms. When these criteria were satisfied, the toxoid would be Seitz-filtered, tested for sterility and submitted to the following final tests. Five cc was injected subcutaneously into a normal guinea-pig, 0.5 cc intraperitoneally into a normal mouse, and 0.1 cc subcutaneously into a normal human being, in order to detect the presence respectively of excess of nonspecific toxic substances, of antiseptic, or of whatever might make the toxoid unsuitable for injection into human beings. The antigenicity of the final product was verified by provoking therewith an active immunity in the normal rabbit against staphylococcus toxin.

PLAN OF TREATMENT

Preliminary animal tests indicated that if the toxoid was to be injected subcutaneously, a slowly increasing

dosage at intervals of from five to seven days was likely to provoke the best response in human subjects. The plan of treatment finally adopted, and in essentials always adhered to, was as follows. The initial dose of 0.05 cc was given subcutaneously into the arm above the deltoid muscle insertion. Successive doses of 0.1, 0.15 and 0.2 cc were given by the same route every five to seven days. Before the first injection of the toxoid, and again a few days after the fourth injection, 2 cc of venous blood was taken from the patient and allowed to clot. The serum was pipetted off, inactivated by heating at 56 C for thirty minutes, and its content in staphylococcus antitoxin then estimated by titration of its antihemolytic power against a staphylo toxin of known hemolytic unitage, with the use, as an indicator, of a 1 per cent suspension of "packed" rabbit erythrocytes in physiologic solution of sodium chloride.⁹

By this method, after the four doses of antigen had been given, an increased amount of circulating staphylococcus antitoxin was in every instance demonstrable, which was, in general, commensurate with the degree of clinical improvement that had meanwhile occurred. The first series of injections was usually supplemented by a further series of four or more larger doses, the antitoxin content of the serum being again assayed as occasion seemed to demand, and in every instance a few days after the complete course of injections had been given. Patients were required to report, as far as possible, at monthly intervals thereafter, in order that their continued freedom from recurrence of infection might be ascertained and a blood specimen taken for estimation of circulating antitoxin.

Treatment with the toxoid was undertaken only when the clinical signs of a primarily staphylococcic infection were confirmed by the isolation from the infected site of a toxigenic staphylococcus in pure or almost pure culture. The hemolytic power of toxins derived from such strains, against a 1 per cent suspension of rabbit erythrocytes in physiologic solution of sodium chloride, varied between the wide limits of 5 and 10,000 hemolytic units per cubic centimeter, the majority of strains yielding toxins of between 200 and 1,000 hemolytic units per cubic centimeter. Since no obvious correlation was noted between the type or severity of the clinical infection and the capacity of the causal organism to produce toxin in vitro under the standard conditions of the method used, and since the toxins produced by different staphylococcus strains appear to possess qualitatively the same antigenic potentialities, no advantage was considered likely to derive from preparing a separate autogenous toxoid for the immunization of each patient. A toxoid was therefore made from the pooled, highly potent toxins derived from ten selected strains.

The limited space available precludes any attempt to give the clinical history and serologic data in each of twenty-eight patients suffering from intractable staphylococcic infection who have been successfully treated with a series of injections of this toxoid. A brief summary of the results obtained is therefore given, an outline of one particularly interesting case being offered as an epitome of the others.

Sixteen patients, aged from 11 to 60 years, had severe boils. In some instances, boils had recurred in crops for several years. In others, patients had never been free from boils for many months. An average of 2 cc of staphylococcus toxoid was

⁹ There is now abundant experimental evidence supporting this as an authentic method of staphylococcus antitoxin assay. It was chosen to titrate the antihemolytic power of the serums rather than their anti-dermonecrotic or flocculating power, because of the greater simplicity and speed of the first method.

given by subcutaneous injection in eight doses over a period of six weeks. Two patients received only four, and two others received as many as twenty doses. The average initial titer of circulating staphylococcus antitoxin was around 8 antihemolytic units, whereas in a group of healthy persons of equivalent age the average titer would be around 20 or 30 antihemolytic units. All patients have now been free from boils for periods ranging at the time of writing from two to eight months, and their circulating antitoxin titer, although fallen from the maximum attained, is still, on an average, tenfold higher than it was initially.

There were six cases of a severe type of pustular acne with furunculosis in adolescents, all of at least two years' duration. The same statements apply as in the first group, in regard to the average amount of toxoid injected and the titers of circulating antitoxins present before and after treatment. All cases resulted in clinical cures.

One case of generalized acute bullous impetigo in a Negro, aged 36, with an initial antitoxin titer of 80 antihemolytic units, cleared up with surprising rapidity after five injections of staphylococcus toxoid (15 cc. in all) had raised his titer to 160 antihemolytic units.

Single cases of recurrent eczematization of skin, of severe pustular dermatitis, and of extensive abdominal cellulitis following laparotomy (all of staphylococcal origin) healed within so short a period after institution of the toxoid injections as to leave no reasonable doubt regarding the benefit they had received from this immunizing procedure.

In two cases of recurrent staphylococcal sinusitis, one of exceptional severity and long duration, the symptoms of infection were lost after the titer of circulating antitoxin had been much increased by a series of toxoid injections.

The following, more detailed, account of recurrent boils, with angioneurotic edema may perhaps be justifiably given.

A woman, aged 34, a high school gymnasium teacher, referred by Dr. E. J. Trow of Toronto and seen early in July, 1932, for about seven years had been subject to recurrent boils, which appeared chiefly in the winter months but were liable to follow overexertion in any season. She had "over 500 boils within three years of their onset, including thirty carbuncles having seven or eight outlets, and several finger infections requiring long incisions. Then gave up counting." Large, edematous swellings of the face and limbs, causing considerable local distortion and pain, were also liable to occur at times when a boil was developing there. She was quite incapacitated from her work on such occasions, and during the winter months a week rarely passed without at least one day's absence. She had tried countless previous remedies, including vaccines, without benefit resulting.

The initial antitoxin titer of her serum was between 12 and 16 antihemolytic units. Weekly injections of toxoid were instituted, and nineteen injections (totaling 105 cc. of toxoid) were received. The patient gave an unusually slow response to the antigen. Thus, although her titer of antitoxin rose to 60 antihemolytic units after four doses (0.55 cc.), it was still at the same level over three months later, at which time fifteen doses (6.3 cc.) of toxoid had been given. The 60 antihemolytic units in her serum allowed her to enjoy a far greater degree of freedom from infection than heretofore, but this amount was evidently not quite sufficient to afford complete immunity. Two modified infections occurred during these three months, one a whitlow, from which, on incision, a small bead of pus was obtained, yielding a pure culture of highly toxigenic *Staphylococcus aureus*, and the other a small boil on her chin.

However each of the last four doses given resulted in a considerable increment in the titer of circulating antitoxin, which jumped to 120, 140, 200 and 260 antihemolytic units successively, when estimated at weekly intervals. Since the time when the titer rose from 60 to 120 antihemolytic units (now over two months ago) the patient has been entirely free from staphylococcal infection. She has had none of the characteristic edematous swellings since the treatment began, and has this year also felt much better in general health.

The only further comment I wish to make regarding this case and applicable to several of the others treated, is that although "sensitization" to some product of the staphylococcus

would appear to have been present as well as susceptibility to infection by the coccus, the patient suffered no general or focal reactions of any sort throughout a long series of toxoid injections. My experience has been that although patients not uncommonly have, in fact, local pain, swelling and redness of the arm on the day following the injection, particularly after the first dose or two, the discomfort is never of serious magnitude and is usually negligible. Further, I have now given more than 500 subcutaneous injections of staphylococcus toxoid to human patients of all ages from 10 to 67, with not more than ten complaints of slight subsequent malaise and headache.

The results recorded would appear to indicate the ready amenability of certain types of staphylococcal infection to the specific treatment given. About thirty other cases of various kinds are under treatment, and it has been remarkable to note the beneficial effects following two or three injections of the toxoid in the majority of these. Cases of recurrent and persistent boils, in my experience, invariably respond to toxoid injections. Sixteen patients of this type have either remained free from recurrence for periods that are of long duration, when compared with their intervals of freedom from infection prior to immunization, or proved able rapidly to overcome a crop of boils that had long resisted various kinds of previous treatment, after two or three injections of the toxoid had been given. In other words, alleviation or disappearance of intractable infections of long duration occurred always too soon after a few subcutaneous injections of the toxoid had been given, to be attributed to the effects of favorable fortuitous circumstances, a conclusion that seemed to me partly to justify publication of this preliminary report.

Six patients with pustular acne and furunculosis quickly ceased to have further furuncles, and the pustular factor in their acne soon afterward became negligible. Among the remaining cases treated were a variety of less common types of staphylococcal infection, but the results obtained by immunization with the toxoid were always very favorable. While the number of cases of all types could have been multiplied manifold, treatment was, as a rule, confined to those I could myself conveniently control and observe, in order to insure prompt and accurate administration of the injections and faithful withdrawal of blood whenever required for antitoxin assay.

COMMENT

At the time of writing, rather less than a year has passed since the earliest of this series of patients began to receive injections of staphylococcus toxoid. Sufficient time has obviously not yet elapsed for any confident statement to be made regarding either the duration of the immunity they appear to have gained, or the nature of the future changes that may occur in their serum content of staphylococcus antitoxin. It is arguable that immunization with staphylococcus toxoid against localized staphylococcal infections is a procedure analogous to antidiphtheria prophylaxis by diphtheria toxoid injections. But one cannot presume that the analogy should be pressed so far as to cover the duration of the immunity conferred by these two measures. However, even if the immunization procedure described in this paper were efficacious only for the cure or prevention of an attack of boils in a susceptible person, staphylococcus toxoid would still be of therapeutic and prophylactic value. The deleterious effects of an attack of boils may be far more wide reaching than is generally imagined, and those who have suffered from such an

attack will acknowledge the serious degree of disability and disturbance of general health that may be occasioned. Boils should be regarded as potential sources of devastating, and maybe fatal, generalized infections, rather than as mere manifestations of parasitism on the part of an almost ubiquitous and comparatively inoffensive micro-organism.

A number of facts relevant to the problem of immunity and susceptibility to staphylococcic infection have come to light during the course of this investigation, but they may more appropriately be discussed at a later date, when a less provisional elucidation of them may be available. However, one or two general observations may perhaps be placed on record now. For instance, it is found that patients who have long suffered from the most common and indubitable form of staphylococcic infection, namely, boils, show no more and often less circulating antitoxin than do healthy persons of the same age. In other words, repeated superficial infections of this type give no antigenic stimulus capable of evoking antitoxin production, whereas, if the patient is given three or four small subcutaneous injections of staphylococcus toxoid over a period of two or three weeks, the titer of his circulating antitoxin will rise as a rule well above the titer encountered in healthy persons of the same age. By the end of this period, a considerable degree of clinical improvement will be evident and a further series of injections will result in apparent cure.

On the other hand, cases of recurrent staphylococcic infection involving deeper tissues, such as bone and muscle, show a greater amount of circulating antitoxin than is usually found in normal persons of similar age. Yet despite their more than average amount of circulating antitoxin, such persons remain subject to recurrences of staphylococcic infection. It is certainly possible to raise the serum antitoxin titer of such patients to a still higher figure by giving them a course of injections of staphylococcus toxoid. Among the patients now under treatment are included both children with recurrent migratory osteomyelitis and adults with a long history of repeated staphylococcic abscesses of bone and deep soft tissues. These have responded very well serologically to the antigenic stimuli that have been deliberately applied to them. For example, a man, aged 40, with recurrent staphylococcic abscesses for four years, increased his titer of circulating antitoxin from an already high value of 100 antihemolytic units to 3,000 antihemolytic units, after a total of 2 cc of toxoid had been injected subcutaneously over eight doses at intervals of five days. The future history of such patients will be followed with interest.

I do not suggest that there is a particular titer of circulating antitoxin above which all persons could safely be considered immune to any form of staphylococcic infection, for the staphylococcus is perhaps the most adaptable of all common pathogenic micro-organisms. But though it is able to multiply in vitro in concentrated horse serum of an antitoxic titer considerably higher than the maximum I have yet succeeded in provoking in any human patient, the clinical results appear to indicate that the staphylococcus is no longer able to maintain itself in human tissues when the antitoxin circulating in the blood is raised by the method described to a titer far higher than that initially present. In patients so immunized, it is possible that the leukocidal and necrotizing exotoxin is at once neutralized on liberation from the infecting staphylococci, permitting both the leukocytes to assert their natural

phagocytic function and also the tissues to undergo a reparative reversion to a gel state affording no pabulum for any surviving staphylococci.

A further analysis of the factors that probably operate for and against staphylococcic infection in human beings must be deferred to a later date.

SUMMARY

1 Staphylococcus strains isolated from infected human patients produce, under appropriate conditions, a true exotoxin having characteristic destructive effects on the cells and tissues of experimental animals.

2 Staphylo toxin can be rapidly detoxicated by the addition of 0.3 per cent solution of formaldehyde (U. S. P.), yielding a highly antigenic toxoid which may be safely injected subcutaneously into human patients.

3 A few small subcutaneous injections of staphylococcus toxoid given at intervals of from five to seven days will rapidly provoke an increased amount of circulating staphylococcus antitoxin both in experimental animals and in man.

4 The content of staphylococcus antitoxin in any serum may be easily estimated by titrating its antihemolytic power against a staphylo toxin of known hemolytic unitage, using as an indicator a 1 per cent suspension of "packed" rabbit erythrocytes in physiological solution of sodium chloride.

5 Twenty-eight patients suffering from intractable, persistent or recurrent staphylococcic infection, including sixteen severe cases of boils, received a series of injections of a toxoid prepared from several strains selected for their high toxigenicity. Alleviation, and then apparent cure, of their infections occurred soon after the commencement of the treatment in each case and could be correlated with an increased titer of circulating antitoxin.

SIMPLE TEST FOR PREGNANCY USING IMMATURE FEMALE ALBINO RATS

PREMATURE ESTABLISHMENT OF VAGINAL ORIFICE BY INTRAPERITONEAL INJECTIONS OF URINE OF PREGNANT WOMEN

G. LOMBARD KELLY, M.D.

Professor of Anatomy, University of Georgia Medical Department
AUGUSTA, GA

Certain rodents, notably the guinea-pig, the rat and the mouse, do not have patent vulvas until about the time of sexual maturity. It has been known for a long time that in the guinea-pig the vaginal orifice becomes closed after each heat period and remains so during the anestrus interval and throughout pregnancy as well. In the rat, the opening, once established about the time of sexual maturity, is a permanent one.

The histogenesis of the periodic opening and closing of the vaginal orifice in the guinea-pig was investigated by Papanicolaou and me¹. It was conclusively shown that the opening process is accomplished by increased vascularity and cornification. There is no vaginal closure membrane, but the dorsal and ventral vaginal lips are cicatrized together for an eighth of an inch or more. The process of scar formation in the

Contribution No. 9, series B, from the Department of Anatomy, University of Georgia Medical Department.
1. Kelly, G. L., and Papanicolaou, G. N. The Mechanism of the Periodical Opening and Closing of the Vaginal Orifice in the Guinea Pig, *Am. J. Anat.* 40: 387-411 (Nov.) 1927.

closure process is accompanied by the advent of myriad plasma cells and the formation of fibroblasts

The vaginal opening in the rodent at the first estrus (and subsequently at each heat period in the guinea-pig) is the result of the hyperplasia that is caused by the action of estrin, turned into the circulation by the ovaries

The basis of the experiments reported in this communication is the action of the anterior pituitary

Fig 1—A, site of future vaginal orifice in immature female rat (closed vagina) B, vaginal orifice established

hormone on the immature ovary, as shown by Aschheim and Zondek² and by Smith and Engle³. Since the urine of pregnant women contains a sufficient quantity of a substance that has an action similar to that of anterior pituitary transplants on the ovary, the injection of such urine should cause the stimulated ovaries to produce a precocious estrus

Guinea-pigs, albino rats and albino mice were considered as being possibly suited for the test. The guinea-pig has a cycle more than twice as long as that of the rat or the mouse and its ovary does not respond so quickly to anterior pituitary stimulation, as is shown by Papanicolaou⁴. We found this animal unsuitable for the purpose.

White mice cannot accommodate sufficiently large injections, and the organs are too small for satisfactory observation, so they were likewise considered unsatisfactory

Female albino rats of a certain size are excellent material for this reaction. They are easy to handle, can accommodate large injections of urine intraperitoneally without mishap, and are easy to observe (fig 1)

The site of the vaginal orifice in the immature rat is a slightly crescentic white cicatrix just behind the clitoris (which in all the rodents mentioned herein is traversed by the urethra, as the penis is in the male). At the first opening a small amount of fluid exudes from the opening, which now assumes a round shape. Just before the opening a few strands of epithelial tissue can be seen still holding the lips together. In some cases the escaped fluid dries in such a way as to obscure the fact that the vagina has opened. On examination, if there is not a distinctly closed vaginal site or a patent opening, the animal may be grasped by the neck and shoulder region (not around the abdomen) with one hand and the base of the tail pulled stoutly with the forefinger and thumb of the other hand (fig 2). If the vagina is open, this maneuver will round the orifice out so that the lumen can be seen

MATERIAL AND METHOD

Albino rats raised in our own laboratory were used as long as they lasted. The ages of these were known. When they were used up, rats of definite weights were ordered from a supply house. These orders were rather unusual, and the rats, when delivered, always weighed a few grams more than specified. A demand for such animals in numbers, however, would remedy this inconvenience.

A fine hypodermic needle was used in making the injections. Without removing hair from the abdomen, an area near its center was wet with a swab of tincture of iodine, and after the needle was inserted it was held in such a way as to lie parallel with the abdominal wall (against its inner surface). It is necessary to have an assistant hold the animal firmly by the fore and hind legs.

The urine is kept in refrigeration before injection but is warmed to 40°C just before injection. The temperature of the urine by the time of injection will of course be slightly less than body temperature, the principal purpose being not to introduce ice-cold urine into the peritoneal cavity.

It seems remarkable that an animal weighing only 25 Gm can accommodate an intraperitoneal injection of 5 cc without harm, but it is nevertheless true.

Merely as a trial to see what would happen, two 30-day old rats were injected as follows with urine from a woman known to be pregnant: January 5, afternoon, 5 cc; January 6, afternoon, 5 cc; January 7, forenoon, 5 cc. The vaginas were still closed, January 7, and were not observed again until the afternoon of January 8, at which time both were completely open. Vaginal smears taken at this time were of the estrous type, one having a few proestrous cells as well. The number of hours elapsing from the first injection until the opening could not be determined because the animals were not observed the night of the 7th or the morning of the 8th. The time from the first injection until the observation of the opening was about seventy-two hours.

January 9, between 4:30 and 5 p.m., six female albino rats, aged from 30 to 35 days, were injected with 5 cc of urine from a woman known

to be gravid. At the same time, six rats of the same age were injected with the urine of a woman known not to be pregnant. (The latter urine was obtained from women in the child-bearing age.) The injections were repeated as follows: January 10, between 9 and 9:30 a.m.; January 10, between 4:30 and 5 p.m.; January 11, between 9:30 and 10 a.m. Six of the twelve animals were considerably smaller than the other six.

Fig 2—Method of holding rat in order to hollow out the vaginal lumen when opening has taken place

⁴ Papanicolaou, G. N. Specificity of Reactions Produced by Injection of Urine from Pregnant Cows into Immature Female Guinea Pigs. Proc. Soc. Exptl. Biol. & Med. 25: 807-810 (May) 1931.

Three each of the larger and of the smaller were used as test animals and three of each size as controls. On the fourth injection, urine from a different pregnant woman was injected into the test animals, the specimen used for the first injections having been used up. The three smallest test animals (weighing about 25 Gm each) died shortly after the fourth injection, with signs of anaphylaxis. These were the only animals lost throughout the experiments. In no other cases were more than three injections given, and in many only two were given.

It is notable, as shown later, that in two test animals a single injection of 5 cc produced openings in less time than plural injections in other animals. Whether a single injection of 5 cc is as efficacious as plural injections remains to be determined. In view of the failure of very large injections of urine into rabbits to hasten ovulation in the Friedman test, the presumption is that a single injection of 5 cc would be sufficient.

TABLE 1—Record of Immature Female Albino Rats Injected Intraperitoneally with Urine from Pregnant Women

Animal	Age or Weight	Injections		Opening in Hours
		Number	Amount	
1T	30 days	3	5 cc	<72
2T	30 days	3	5 cc	<72
3T	30 35 days	4	5 cc	<64
4T	30 35 days	4	5 cc	<64

* Died after fourth injection of 5 cc, the uterus showed definite estrous distention.

In the three animals that died, postmortem examinations revealed typical heat distentions of the uterus. The ovaries were enlarged and contained many follicles. Vaginal smears showed principally proestrous and estrous cells, with a few leukocytes in one specimen.

January 12 in the forenoon, the vaginas of the three living test animals were all open and those of the six control animals all remained definitely closed.

It had been considered possible that the vaginal smear would be of more value than the establishment of the vaginal orifice, but this was not found to be so. There may be sufficient estrin in the quantity of nonpregnant urine injected to initiate changes in the vaginal epithelium directly, but it is probable that the proestrous smears in the control animals is an expression of cyclic ovarian action that is too weak to produce a frank estrus. There is not sufficient estrin in the quantity of urine injected into controls to bring about a frank precocious estrus with cornification and establishment of the vaginal orifice.

Papanicolaou and Blau⁵ demonstrated that the bitch is really polyestrous and has a rhythm of 15-62 days,

which is more strongly expressed every other. This cycle is one fourth of the gestation period—sixty-three days. They were able to intensify the expressions into definite estrus by means of injection of estrin and to bring bitches back into heat shortly after a regular estrous period.

Smears from the test animals will at some time around the opening give purely estrous cells as seen in the copulatory stage. On forcibly opening the vagina of the control animals a majority of proestrous smears were obtained, none showing a majority of estrous cells.

In order to test the effect of one 5 cc injection of urine from a pregnant source, two rats, aged from 10 to 35 days, were given this amount at 5 p. m., January 10. The vagina of one was open at 3:30 p. m., January 12, forty-six hours after treatment. The vagina of the other was found open, January 13, 9 a. m., having probably opened during the night. The gross elapsed time was sixty-four hours.

Three females from a litter of six 16-day old females were available from our own colony. The vagina of one of these was forcibly opened and a smear was made. A few non-nucleated (estrous) and some nucleated (proestrous) cells were found, but no leukocytes. This corroborated the uselessness of depending on smears for this animal was so small it had not long been covered with hair. Other older female albino rats were found to have proestrous smears after no injections whatever.

Of the remaining two small 16-day old females, one was given 3 cc of urine from a pregnant woman intraperitoneally on two consecutive days and the vagina opened within ninety-six hours, though the exact time was not determined. The vagina of the littermate control, which received the same amount of urine from a nonpregnant woman, failed to open.

Two groups of eleven rats each were next injected with urine from pregnant and nonpregnant sources respectively, each animal receiving 5 cc as follows: January 18, between 10 and 10:30 a. m., and between 8:30 and 9 p. m., January 19, between 9:30 and 10 a. m. The vaginas of all the test animals were found open in from seventy-one to eighty-three hours. None of the vaginas of the control animals opened.

These animals had been ordered from a dealer to be delivered weighing from 20 to 30 Gm. At the completion of the tests, the actual weights varied from 29 to 48 Gm, the average weight being 35.7 Gm. The weights on arrival were probably 2 or 3 Gm less.

In their monograph on the estrous cycle of the albino rat, Long and Evans⁶ state that the average age of an animal at the establishment of the vaginal orifice is 76.5 days. In a group of 200 rats, the low and high limits were 34 and 109 days. The average weight of the animal at the time of the vaginal opening is 35 Gm. This may be of equal importance.

We found that to a large extent the number of animals in a litter determined the weight at a certain age. For example, rats in two litters of ten and nine weighed about 25 Gm each at 30 days, while rats in two litters of two and one weighed about 45 Gm at the same age.

It was also observed that the older and larger the rat, the shorter was the time required for the opening of the vagina. In order to take advantage of the

of rats as large as possible (without danger of natural establishment of the vaginal orifice), two groups of animals were ordered as follows: one dozen between 30 and 40 Gm, and one dozen between 40 and 50 Gm. The actual weights on arrival were between 38 and 49.5 Gm for the first group and between 50 and 57.5 Gm for the second.

Of the first group, two animals had maturely opened vaginas. One weighed 42.5 Gm and the other 49.5

Gm. Of the second group four had open vaginas and weighed respectively 51, 53, 54.5 and 56 Gm. All of these animals were discarded.

In order to determine the opening times of animals of this size, the eighteen remaining animals were injected with 7.5 cc of pregnancy urine at 12 noon and 6 p. m., January 27. All the openings occurred in from twenty-one to seventy-five and one-half hours, as shown in table 2.

Undoubtedly, the animals with openings in less than forty-five hours were getting ready to open naturally. The remainder, no doubt, were opened prematurely by the injections. It is quite evident that if the former are disregarded, the average opening time of the latter is less than that of the younger animals, previously reported. Apparently, the more nearly mature the ovary, the quicker its response to the anterior pituitary-like element in the urine.

Since the amount of estrin excreted in the urine of pregnant women is said to be greater after the third or fourth month than before, it might be a direct aid to the anterior pituitary-like substance in establishment of the vaginal opening, though doubtless no such aid is required. In view of the fact that the opening is brought about by the increased production of estrin in the stimulated ovary, it is not worth while to remove the estrin from the specimen to be tested. If an ovarian cyst were suspected, this would possibly be necessary, since the amount of estrin in the urine might be thus greatly increased.

It is obvious that animals weighing not more than 40 Gm should be used for the test and animals weighing between 30 and 40 Gm are suggested as most suitable. If animals of known ages could be purchased from reliable dealers, it is probable that even heavier ones could be used with safety, possibly up to 50 Gm. Of course, the animals should be closely scrutinized before injection to make sure that the vaginas are of the immature closed type. Cystic ovarian disease in young rats might account for the very early openings in Long and Evans's series, though it is more likely that such specimens were from very small litters and weighed more than the average animal of their age. Such animals naturally should be discarded.

The urine should be given in two 5 cc injections, one in the morning and one in the afternoon of the same day. The urine should be from the specimen first passed on arising.

It is advisable that two rats be used for each test, requiring that both vaginas open within ninety-six hours as a positive test. As a rule, the opening will occur between seventy-two and eighty-four hours. This means that if the injections are made on the morning of a certain day the result of the test can be read following. This is longer than is required for the Friedman test, which on an average is about forty-eight hours, and is shorter than required for the Zondek-Ashheim test, which takes four or five days.

The results of all the injections are summarized in the tables. The vaginal orifice was established without exception in the animals that received the pregnancy urine and in no case was it established in an animal that received nonpregnancy urine.

The advantages of this method are obvious: the ease of intraperitoneal injection, the convenient size of the animals used, the economy in raising or purchasing test animals and the facility of observing the result of the test without killing or operating on them.

SUMMARY

1 Intraperitoneal injections of from 5 to 15 cc of urine from pregnant women will cause premature establishment of the vaginal orifice in the albino rat weighing from 30 to 40 Gm, usually within from seventy-two to eighty-four hours.

2 Intraperitoneal injections of the same amount of urine from nonpregnant women will not cause such premature opening of the vagina.

TABLE 3—Record of Immature Female Albino Rats Injected Intraperitoneally with Urine from Nonpregnant Women in Which Vagina Remained Closed

Animal	Age or Weight	Injections	
		Number	Amount
10	30-35 days	4	5 cc
20	30-35 days	4	5 cc
30	30-35 days	4	5 cc

160	38 Gm	3	5 cc
170	35 Gm	3	5 cc
180	31.5 Gm	3	5 cc

3 Two animals should be used and the opening of the vaginas of both is read as positive, of one, as doubtful (the test should be repeated), of neither within ninety-six hours, as negative.

4 If the vagina is open and the orifice obscure, one may see it by holding the animal by the neck and shoulder region and pulling strongly on the base of the tail. In this maneuver the abdomen should not be compressed.

5 The main advantages are the simplicity of the test and the ease of reading the result.

THE SUSCEPTIBILITY OF HEMOLYTIC
STAPHYLOCOCCI TO BACTERIOPHAGE

FELIX D'HERELLE, M.D.

AND

M. L. RAKIETEN, M.D., PH.D.
NEW HAVEN, CONN.

A portion of the problems that we are investigating have, because of their nature, led to a study of several polyvalent staphylococcus bacteriophages obtained from various sources. The recent report of Straub and Applebaum¹ on commercial bacteriophage products confirms our earlier studies.²

During the past two years we have tested polyvalent staphylococcus bacteriophages on 121 strains of staphylococci isolated from individuals with carbuncles, furuncles, sinusitis, osteomyelitis and staphylococcus septicemia. Seven of these strains of staphylococci, all nonhemolytic, are not susceptible to any of the phages we have used against them. These strains of bacteria were isolated from long-standing cases of furunculosis (one), sinusitis (four) and osteomyelitis (two). All these organisms grow very well on plain Savita medium and multiply as rapidly at 20 C as they do at 35 C.

Seventy-one of the strains produced strong hemolysis of rabbit, guinea-pig or human blood when they were cultivated on Savita agar to which 4 per cent blood had been added. With one exception all these cultures of hemolytic staphylococci (*albus* and *aureus*) were found to be susceptible to polyvalent staphylococcus bacteriophages on the first contact. The one resistant culture was isolated from an abscess in a patient who was being treated for diabetes. This culture developed colonies on rabbit blood agar which were very similar to those produced by a typical pneumococcus type II, both in size and in degree of hemolysis. However, when a portion of a colony or a loop of a fresh broth culture was stained in the usual manner, the microscopic picture was that of a staphylococcus.

The remaining twenty-one strains were nonhemolytic and were also susceptible to bacteriophagy, but in several instances it was necessary to make repeated contacts with bacteriophage before complete lysis was effected.

In 1926, Epstein and Feigin³ reported that, in a routine examination of staphylococcus cultures, all of the hemolytic strains (thirty-one) were resistant to bacteriophagy and that there was a definite relation between the amount of hemolysis produced and the resistance to lysis by bacteriophage. They employed horse blood agar. All their nonhemolytic staphylococci (ninety-one cultures) were phage susceptible. In 1930, McKinley and Cámara⁴ reported that seven strains of hemolytic staphylococci resisted the action of polyvalent staphylococcus bacteriophage supplied by Dr. Larkum. They agreed with Epstein and Feigin that hemolytic staphylococci were resistant to bacteriophagy.

The results that we obtained with our phages were so different from those reported by the investigators mentioned previously that we procured some horse blood and tested many of our susceptible hemolytic strains of staphylococci on a medium containing 4 per cent of horse blood. All of the twenty strains that were tested were found to be hemolytic on this medium as well as on rabbit blood agar. Furthermore, the cultures from the horse blood medium were as susceptible to our phages as they had been from other mediums.

We have recently obtained a sample of polyvalent staphylococcus bacteriophage from Dr. Larkum and find that it is able to lyse all of the hemolytic cultures of staphylococci against which it was tested (twenty-four).

It is well known that most cases of acute infection with the staphylococcus are caused by the hemolytic strains. It has also been stated⁵ that chances of success with phage therapy are much better in cases of acute infection than in cases of long-standing chronic infection. The susceptibility of hemolytic staphylococci to bacteriophage supports this statement. We have also isolated nine strains of hemolytic *Bacillus coli* and have found that these strains also are strongly attacked by coli bacteriophages.

CONCLUSIONS

1 Hemolytic staphylococci are particularly susceptible to bacteriophagy.

2 Resistant strains of staphylococci are generally of the nonhemolytic type.

310 Cedar Street

PELLEGRINI-STIEDA'S DISEASE

A REPORT OF ONE CASE SURGICALLY TREATED

JACOB KULOWSKI, M.D.

IOWA CITY

Pellegrini-Stieda's disease is characterized by a semilunar-like bony formation in the region of the internal condyle of the femur and is always traumatic in origin. The condition has been and is being reported in the foreign literature. This is the first case to be described in the English literature. My object is to report one surgically treated case in detail and to discuss briefly the condition in general.

Pellegrini in 1905 called attention to a traumatic ossification of the collateral tibial ligament of the knee. The same year, Kohler reported a similar case and in 1907 Stieda, unaware of the previous work, again called attention to a semilunar-shaped calcification seen about the superior border of the internal epicondyle of the femur. Pellegrini thought that the disease was traumatic. Stieda believed it was due to a fracture with a detachment of a small particle of bone at the moment of injury, with subsequent calcification taking place in the ligament. König, Kohler, Pfister and Ewald were definitely of the opinion that the calcification was a fractureless callous formation and that it was the end result of periosteal proliferation, secondary to a tear of the ligaments and tendons at that point. They support their contention with the fact that the process never appears within less than two or three weeks following the injury. Most observers feel that it can be caused

by either direct or indirect trauma. There is still some controversy over the origin of this formation, some believing that it is of periostitic origin, others that it arises from the surrounding connective tissues. I believe that the condition is similar to myositis ossificans. More than 136 cases have been reported in Germany and Italy. It is chiefly unilateral. The clinical course varies considerably in severity, sometimes resulting in permanent disability.

Clinically, the cases run a similar course in that the patient gives a history of a fairly slight trauma and, if roentgenograms are made immediately following the trauma, there is no evidence of dislocation or fracture. However, if the symptoms fail to subside and the patient is examined at the end of about two weeks, there will be found a typical semilunar-shaped calcification. This shadow is usually crescent shaped, though it may be somewhat fusiform or elongated or triangular. The lesion may heal spontaneously. Some believe there is no need for operative intervention, as the condition has a tendency to recur.

REPORT OF CASE

History—G. B., a white man, aged 29, seen in the outpatient clinic, Sept. 2, 1932, complained of pain and disability in the left knee of three months duration. The onset of symptoms followed a traumatic incident during a ball game in which he participated. Another player collided with the patient and struck him tangentially on the left knee. This mechanism of injury usually causes some internal derangement of the knee. There were no immediate symptoms, and he continued his game.

That night he experienced definite pain over the medial side of the left knee. This was rather sharp and aching in character and was progressive. Weight bearing aggravated the discomfort and occasionally enforced bed rest. Weather changes had no influence on the course of the disability. Occasionally a moderate redness appeared about the region of the internal condyle suggesting inflammation, although he does not think that he ever had definite fever or chills. There had never been any "locking," "slipping" or "giving way" of the knee joint. There had lately developed some limitation of the joint range of motion. A sense of swelling and induration had persisted for the past several months over the medial femoral condyle. He had lost 15 pounds (6.8 Kg.) since his injury but had no subjective general bodily complaints or other joint symptoms. He had had no treatment for the local disability except for several enforced periods of rest due to the local disability.

The functional, past and family histories were essentially negative.

Examination—The patient was well developed and well nourished and apparently not acutely ill. The systemic examination showed nothing remarkable.

He walked unsupported but with a left-sided limp. The left knee was five-eighths inch greater in circumference than the right, but the left thigh also exhibited $1\frac{1}{4}$ inches atrophy and the left calf three-eighths inch. The range of motion of the left knee was from 175 degrees of extension to 80 degrees of flexion. Beyond this range passive attempts at further motion caused some pain in the joint.

A circumscribed tumor-like swelling was noted and could be palpated over the internal condyle of the left femur, which was tender to pressure. This was rather hard and apparently was firmly attached to the deep structures in this region. The skin over this infiltration was slightly discolored but freely movable. Abduction of the leg caused some discomfort in the region of the internal lateral ligament. There were no other evidences of internal derangement of the knee.

Roentgenograms (in the anteroposterior view) showed the typical semilunar-like bony formation about the medial condyle. The bony outlines of the lower end of the femur were clearly defined and a clear space was present between the mass and the periosteum of the femur. The bony formation was not of

uniform consistency but was somewhat variegated in structure. Its margins were indistinct and irregularly outlined. Its lower limit might well have involved the upper attachment of the medial lateral ligament. No definite bony trabeculation could be made out within the ossification. No other visible changes were noted (fig. 1).

Laboratory examinations revealed urine, normal, Wassermann reaction, negative, coagulation time, four minutes, hemoglobin, 75 per cent (Tallqvist), red blood count, 3,830,000, white blood count, 10,000.

The patient received a brief period of treatment with diathermy, massage and an elastic bandage but with no local improvement. Operation was finally indicated because of the long duration of the condition and the apparently fully developed character of the bony formation.

Operation—September 8, under ethylene gas anesthesia and with a thigh tourniquet, a slightly curved incision was made over the palpable mass in the region of the medial condyle of the left knee. The dissection was carefully continued through the tendinous structures down to the bony mass, which measured about 4 cm. in length and 1 cm. in diameter. This formation infiltrated the tendons of the adductor magnus and vastus medialis but was nevertheless clearly defined. It was intimately related to the internal lateral ligament but did not actually involve it. It was not united to the bone or periosteum of the condyle and could be dissected and shelled out, although

Fig. 1—Preoperative anteroposterior view of the knees showing the more or less typical semilunar-like bony formation in the region of the internal condyle of the left femur.

no definite capsule was present, without injury to important structures. The wound was closed in layers, with interrupted sutures, fine chromic for the deep structures, fine catgut for the subcutaneous tissues, and dermal for the skin. A dressing and long leg cast were then applied. The entire bony mass was fixed and decalcified, and serial histologic studies were made.

Postoperative Observations—At the time of this writing, the patient has been observed about four months.

For several days after the operation, he had a slightly elevated temperature but was comfortable. The wound healed in about ten days, and the cast was removed. Physical therapy was instituted, and he was allowed gradual supported weight bearing. He was discharged from the hospital, September 17, and was instructed in home physical therapy. The postoperative roentgen examination demonstrated the complete removal of the bony formation. Unfortunately, this film has been lost, and no illustration could be made of it.

October 6, the patient was allowed to begin full weight bearing unsupported. The range of motion was then from full extension to 90 degrees of flexion. The patient was symptom free and well satisfied with the result of operation (fig. 2).

December 2, he walked without any support but with a slight symptomless limp. The region of the medial condyle is slightly enlarged and demonstrates an apparent valgus of the knee (fig. 2). There is no tenderness over this region, and the knee is stable. The range of motion is from full extension to 100 degrees of flexion. Serial roentgen examinations show

the progressive recurrence of the bony formation. It is now more extensive than the original but not nearly so dense or well defined (fig 3).

Histologic Description of the Bony Mass Removed at Operation (by Dr Ernest Freund)—The bony mass consisted of a rather dense irregularly distributed substantia spongiosa with the marrow spaces filled by fibrous tissue. This fibrous tissue was rich in large thin walled vessels. The marrow spaces were much larger in the central part of the mass, which was certainly the older portion, in which the spongy bone had undergone changes, resulting in its reduced density. The fibrous tissue itself was rather loose and contained a few fibers, between which were spindle-shaped and astriform cells, and in some places small groups of lymphocytes. The older central portion exhibited an even looser fibrous marrow, in which here and there appeared small groups of fat cells, showing that the fibrous bony marrow had been reconquered by the fatty marrow, a fact well illustrated in fractures in which bony trabeculae with fatty marrow eventually appear in the fibrous callus.

Because the growth of the mass occurred naturally on its free peripheral surface, this region offered an opportunity to observe different kinds of bony growth. Inspection of this border revealed three definite types of bone growth: primitive infiltrative bone growth on the basis of connective tissue, bone formation which was callus-like in character, and endochondral formation of bone.

The infiltrative type was the most common to be observed and occurred on the border between the bony mass and the tendon-like, tough connective tissue. Here the connective tissue was infiltrated in a very irregular manner by clear red homogeneous substance. In this were deposited lime salts as it approached the bony border. This was a primitive type of ossification on the basis of connective tissue (fig 4). In the first state, osteoid tissue is formed which is transformed to real bone by the deposition of lime salts. Owing to the gradual zone of bone transformation, the actual borderline of the bony portion was not clearly depicted in these actively engaged situations. There was a gradual continuous passage, from bone into connective tissue, and even more strikingly did the connective tissue fibers merge into the bone tissue, thus forming the so-called fibers of Sharpey.

Fig 2—A, range of motion about one month after operation, B, appearance of knee about three months after operation

The second type of ossification to be observed was quite callus-like in character (fig 5). At one end of the mass was an extensive area of young hyaline cartilage with very large spherical cells and very little ground substance between them. In some spots this cartilage tissue showed a structural continuity with primitive osteoid bone tissue, which soon became calcified and underwent changes by resorption and new formation. This passage from one tissue into another must not,

however, be interpreted as a direct metaplasia from cartilage to bone. Based on V Ebner's explanation, it is known that this is not a genetic continuity but merely a local continuity in which both bone and cartilage tissues are formed at one time from a common basis of connective tissue.

The third, less important, type of bone formation was the endochondral variety of cartilage ossification. It was a rather primitive type, without the formation of a proliferation zone of

Fig 3—Appearance of left knee A, about one month after operation, B, about three months after operation

cartilage cells. Instead, there was a very primitive discontinuous zone of preparatory calcification. After the intrusion of the cartilage by small vessel sinuses, there was a resorption of the calcified cartilage. On the surface of the remaining cartilage there was then apposition of bone tissue by osteoblasts. The resulting spongy bone showed numerous inclusions of calcified cartilage tissue in the center of the trabeculae. However, in many other situations thick bony trabeculae in the central part of the bony mass showed quite frequently inclusions of primitive bone tissue of a more bluish stain, which contrasted quite markedly with the newly opposed mature lamellar bone, which stained red. The two types of bone were separated by a dark blue lacunar cement line. This picture was produced by repeated processes of resorption of primitive bone by osteoclasts and apposition of mature lamellar bone before the former process was completed.

Because of the exposed situation of this newly formed bony mass, some signs of traumatization might be expected. This was particularly demonstrated at a point at which a bony spur had been formed. Its point was fractured, and the fissure was partially filled with a network of coagulated fibrin. The contiguous thick spongy trabeculae were necrotic and were undergoing an active lacunar resorption from the intact fibrous marrow.

COMMENT AND SUMMARY

In the case of Pellegrini-Stieda's disease reported, the bony formation recurred following operation. This recurrence may have been facilitated by an inadequate period of postoperative immobilization and by

the trauma incident to the operative intervention in tissues already sensitized to the production of bone. From the literature, good results are reported both from conservative and from surgical measures. After four months the patient is symptom free and active in spite of the recurrence of the mass. It is reasonable to assume that no surgical procedure should be instituted before the bony mass has matured, just as in myositis ossificans.

There can hardly be a doubt as to the traumatic origin of the bony mass in this instance. A strain or a partial tear of the internal lateral ligament of the involved knee and its associated tendinous structures, such as the semimembranosus and the vastus medialis, might well have been the primary factor in producing the subsequent bony formation.

This bony formation is essentially very similar to myositis ossificans. It is now quite generally accepted that myositis ossificans is neither a tumor nor an inflammatory process but a so-called metaplastic hyperplasia metatlasia in the sense of indirect transformation of one tissue into another. In this specimen, bony tissue predominates whereas there is generally found in myositis ossificans an equal amount of bone and cartilage. This is due to the fact that this case was of long duration, thus giving sufficient opportunity for a high degree of tissue differentiation. Bony predominance may also have been due to the localization of the process. In this case the bony formation—to judge from the roentgenograms and from the appearance at operation—was clearly para-osteal. It is therefore assumed that this metaplasia occurred only from the tendinous, the ligamentous and possibly even the fascial structures in this region. Such tough fibrous structures are not as conducive to cartilage formation as are the more loose connective tissues of the perimesum and the interstitial septums of musculature, which is the usual situation of myositis ossificans.

nective tissue is able to form bone under certain conditions. The nearer to the bone these tissues are, the more likely are they to lead to such a formation. This is demonstrated in the healing of fractures in which the para-osteal bone production in the interstitial septums and thin muscular fascias is quite considerable, particularly in old people, in whom this type of bone formation is even more important than the periosteal callous formation. This has been clearly demonstrated

Fig 5—Part of the periphery of the bone mass showing the bone growth on the basis of fibrous tissue and the callus-like formation of cartilaginous and bone tissue.

by Freund, who has shown that in fracture of the neck of the femur, endosteal and para-osteal bone productions prevail over periosteal bone production.

These facts are further substantiated by the apparent para-osteal bone formation as seen in the recurrence of the growth. The periosteum was not disturbed during the operation. Immobilization of the limb may lead to the disappearance of the mass, which occurs so frequently in myositis ossificans.

The condition is important from its medicolegal aspect, as all the cases reported have been in adults who sustained their injuries while at work. Because of the tendency to heal (?), hasty judgment should be avoided. Immediate post-traumatic as well as follow-up roentgenograms are essential to establish the diagnosis and prognosis.

In considering the clinical differential diagnosis, practically all of the numerous causes of internal derangement of the knee must be ruled out. Such conditions as total or partial fractures of the medial femoral condyle (rare), and para-osteal arthropathies in paraplegic cases may produce roentgenograms similar to Pellegrini-Stieda's disease.

The treatment of this condition, as advocated in the literature, is the conservative and the operative.

The use of x-rays has been recommended, but sufficient experience is lacking to permit a true evaluation of this therapeutic measure. Diathermy and baking are said to be excellent early measures. Later, to diathermy may be added infra-red and electrical therapy. When the condition goes on to mature bony formation with persistent disability, it is apparent that surgical removal is indicated. This should be accomplished with a minimum amount of operative trauma and should be followed by a carefully observed period of immobilization and physical therapy.

Fig 4—Part of the periphery of the bone mass showing the bone growth on the basis of fibrous tissue.

The definite clear space between the mass and the femoral margin clearly demonstrates that for the bone formation in Pellegrini-Stieda's disease as in all other kinds of para-osteal bone formation—particularly myositis ossificans—there is no need for periosteal participation. None of the conceptions based on tears and dislocations of periosteal tissues into the neighboring tissues as the causes for such para-osteal bony formations are tenable. It is well known that every con-

THE SURFACE TEMPERATURE AND THE MINUTE BLOOD VESSELS OF THE SKIN IN ARTHRITIS

JOSEPH KOVACS, MD

WITH THE COLLABORATION OF
IRVING S WRIGHT, MD
AND

A WILBUR DURYEE, MD
NEW YORK

It is well known that there are two points of view in regard to the etiology of arthritis. One is that the bacteriologic focal infections are believed to be the usual source of the noxious bacteria, the chief exponents of this idea are American workers. The other point of view is based partly on the hereditary and constitutional makeup of the individual and partly on the nervous, gastro-intestinal, endocrine and circulatory disturbances developed during the lifetime of the patient. This theory explaining the etiology of arthritis is predominantly subscribed to in Europe.

In September, 1930 at the congress in Liege the council of the Ligue internationale contre le rhumatisme

Fig 1.—Capillaries of the finger nail fold of a patient aged 38 with osteo arthritis. From an untouched photomicrograph, enlarged from a 35 mm film with a magnification of 176 diameters.

emphasized the importance of circulatory disturbance in cases of rheumatic disease and subscribed to the theory that this is one of the essential factors in the causation and continuance of rheumatic conditions. (It was recorded as the official subject and recommended for further investigation at the congress at Liege in 1930). Until that time very little research work had been carried out in this field.

Only lately, inspired by the work of Lewis, Krogh and Ebbecke on the blood vessels of the human skin and aided by the perfection of the capillary microscope and the thermo-electrical method of measuring skin temperature, has the study of the circulation in the skin of arthritic patients attracted much attention.

Wright and Pemberton¹ state that the surface temperature was below normal in 62 per cent of arthritic subjects, measured on the base of the finger nail. They

stated that the capillary field in arthritic patients usually contained less blood and was lighter in color than in normal persons. These changes, they believe, may be due to the fact that there are fewer open capillaries or that the individual capillaries are smaller. They found that the blood flow under identical conditions was slower and more frequently interrupted in arthritic subjects than in normal persons.

Rhumann² reports that nearly 70 per cent of the patients with muscular rheumatism have anomalies in the finger nail capillaries. He found a vasoneurotic state in several cases. This vasoneurotic state, described by Otfried Muller,³ is characterized by the great lability and instability of the innervation of the muscular system, the capillaries show astonishing variations, for in the same capillary field both narrow loops and some enormously dilated loops may be observed, in some instances there may be dilatations—true capillary aneurysms. Rhumann found, in agreement with Pemberton, a slow and an interrupted blood flow. He considers the globules found at the vertex of capillary loops characteristic signs of poor capillary circulation and obstruction in the blood flow. Our work has led us to accept Klingmuller's⁴ theory that the occurrence of globules is possible only when it is assumed that the width of the blood stream and the width of the capillaries differ, the greater width of the capillaries explaining the whirl movement of the blood.

Lunedei and Corradini⁵ report that in 62 per cent of patients suffering from chronic rheumatism the background of the capillary field was lighter in color than in the normal individual. They found the number of capillaries normal, but in 70 per cent of the cases the capillaries were constricted. Vasoneurotic conditions were present in only 8 per cent. The skin was pale, and the skin temperature ranged between 24 and 28 C.

Weil,⁶ in his microscopic study of the capillaries in 249 arthritic patients, reports a vasoneurotic state in 20 per cent and a poor blood flow in 25 per cent. However, he neglects to explain what he means by a poor blood flow. In his control cases, which were of the nonarticular rheumatic type, he found a vasoneurotic state in 33.3 per cent and a poor blood flow in 12.5 per cent.

Prusik,⁷ studying the blood vessels of the skin in chronic arthritis, found only on the skin above the inflamed joint signs of congestion which seemed to be secondary to venous changes.

RESULTS OF STUDY

We examined eighty cases of chronic arthritis: forty of rheumatoid arthritis and forty of osteo-arthritis. The British classification rheumatoid arthritis and osteo-arthritis was used as the terminology of the two major groups. The patients were examined before treatment of any kind was given, as it is a known fact that the salicylates and other therapy change the skin circulation and affect the capillaries. The point chosen for determination of the capillaries and the surface

determination of sedimentation rate was the same as described by Dawson, Sia and Boots,⁹ the only modification was that we used, instead of 200 mm, 100 mm pipets

The patients were divided into age groups because of the physiologic changes characteristic of advancing years, which must be taken into consideration when looking for the pathologic lesions in chronic arthritis The classification of the capillaries into different groups was our most difficult problem It is generally known that in physiologic conditions there may be in the same capillary field straight, tortuous, small and

quency of tortuosity of the capillaries was increased to 60 per cent The surface temperature was increased to 50 per cent of these patients The results obtained in the sedimentation tests are shown in table 2

A vasa neurotic state, as described by Otfried Müller, was found in 15 per cent of rheumatoid arthritis and in 5 per cent of osteo-arthritis (table 3)

COMMENT

An analysis of the results of our study demonstrated that the density of the capillary bed varied in every individual to some degree We found a definite decrease in the number of capillaries only in rheumatoid arthritic patients on the skin above joints with pronounced local tissue changes, such as Heberden's nodes Fingers with Heberden's nodes have a distinctly decreased number of capillaries which are constricted, reducing the extent of the capillary bed This has a fundamental bearing on tissue nutrition We could not determine whether this disappearance of the capillaries is responsible for

large capillaries, and changes in the rate of blood flow Taking these facts into consideration, we classified our capillary results into definite groups only if over 70 per cent of the capillaries were of a specific type We also examined several capillary fields in different fingers before a definite conclusion was drawn Up to the

the tissue changes, or whether the tissue changes cause the decrease in the capillaries

The size of the capillaries varied within the different arthritic groups. Small constricted capillaries were found in 52 per cent of the cases of rheumatoid arthritis in comparison to the occurrence of 27.5 per cent in osteo-arthritis. This is perhaps due to the con-

Fig 3—Capillaries of the finger nail fold of a patient, aged 45, with rheumatoid arthritis. The marked variation in morphology in the photomicrographs in figures 1, 2, and 3 may be noted. From an unretouched photomicrograph, enlarged from a 35 mm film with a magnification of 176 diameters.

stitutional makeup of the individual, the congenital disturbance of equilibrium between the sympathetic-parasympathetic system causing a widespread increase in the arteriolar and capillary tone. If Nordmann's¹⁰ and Woollard's¹¹ descriptions of a nerve supply enervating the Rouget cells are accepted, the stimulation of such nerve fibers may be the cause of the contraction of the capillaries.

But, on the other hand, the study by Brown¹² on the capillaries of the human skin shows that the nervous innervation is not alone responsible for the contractility of capillaries. He found that cervical ganglionectomy did not dilate the capillaries in any case of arthritis.

It seems that, besides the nervous innervation, general or local physicochemical components may also influence the tonus of the capillaries.

We found an increased tortuosity in 60 per cent of the cases of osteo-arthritis in comparison to 35 per cent in rheumatoid arthritis. We believe that this is a physiologic phenomenon and is due to the higher age average. Numerous studies by different research workers show that, parallel with the age, the tortuosity of capillaries increases. The average age of rheumatoid patients was 44, the youngest 24, the oldest 60. In comparison, the average age of osteo-arthritis was 53, the youngest 27, the oldest 69.

We could not find any connection between the tortuosity of the capillaries and the severity of the clinical symptoms.

The velocity and continuity of the blood flow gave nearly the same results in the different types of arthritis. We found a slow blood flow in 65 per cent of the patients with rheumatoid arthritis and in 52.5 per cent

of those with osteo-arthritis. Most patients with severe clinical symptoms had a slow blood flow.

We found a close connection between sedimentation and rate of capillary blood flow. In all cases in which we found a high sedimentation rate we found also a slow blood flow. The fact that an increased sedimentation is parallel with increased viscosity is evidence in favor of the conclusion that the rate of blood flow in the capillary circulation is influenced somewhat by the viscosity (physicochemical changes) of the blood. It was impossible to find any connection between the rate of blood flow and the tonus and form of capillaries.

We could not find any connection between the continuity of the blood flow and the sedimentation rate.

The surface temperature in 51.25 per cent of the chronic arthritic subjects was on an average lower than that of normal persons. This explains why arthritic patients often complain of numbness and cold hands and feet. The surface temperature, Foged¹³ reports, ranges in normal persons, measured on the finger nail bed, between 32 and 33 C. We found in rheumatoid arthritic patients the lowest temperature to be 20.2 C, in osteo-arthritis, 22.2 C.

All arthritic patients who had a low surface temperature had a slow and sometimes interrupted blood flow. It seems to us that the temperature of the finger nail bed under similar outstanding conditions varies according to the blood flow. In figure 4 the curves of the surface temperature and of slow blood flow are nearly parallel. We found the average lowest temperatures in rheumatoid arthritis between the ages of 31 and 40, and in osteo-arthritis between the ages of 41 and 50.

CONCLUSION

As observed in this series

1 In the region of pronounced tissue changes such as are found in Heberden's nodes and swelling of the

Fig 4—Percentage of subnormal surface temperature (dash line), slow blood flow (solid line) and interrupted blood flow (dot and dash line) according to age in A, rheumatoid arthritis and B, osteo-arthritis.

joints, we observed a definite decrease in the number of capillaries.

2 In the rheumatoid type of arthritis there is a higher percentage of small constricted capillaries than in osteo-arthritis, owing possibly to the constitutional makeup of these individuals.

CARCINOMA—JAISOHN AND JORDAN

1021

- 3 In the cases observed, the rheumatoid type of arthritis has in 52.5 per cent, the osteo-arthritis in 50 per cent, lower surface temperature than the normal
- 4 All patients with a low surface temperature have a slow capillary blood flow
- 5 Increased sedimentation rate is always associated with a slow blood flow and a lowered surface temperature
- 6 The presence or degree of severity of the arthritis is not constantly reflected in the capillary or temperature changes
- 7 Although changes from normal do occur in the skin capillaries and skin temperature in many cases of rheumatoid arthritis and osteo-arthritis, because of the lack of consistency in these observations we cannot consider that they are uniformly responsible for the pathologic changes found in these conditions. Furthermore, it is not established that the condition of the capillaries of the nail fold is paralleled by the condition of the capillaries supplying the joints

CARCINOMA OF THE EPIDIDYMIS PHILIP JAISOHN, MD AND E V JORDAN, MD CHARLESTON, W VA

The infrequent occurrence of malignant tumors in the epididymis, particularly carcinoma, can be judged by the paucity of literature on the subject. Recently we found a case of primary cancer of the epididymis in the course of our routine work. We looked up the literature on the subject, as we had never seen a case before. To our surprise we found only twenty-one cases of primary malignant tumors of the epididymis reported, of which fifteen are sarcomas or teratomas of various sorts and six carcinomas. Three of the six are of doubtful histologic descriptions for carcinoma, which leaves only three authentic primary cancers in this organ as far as we could find. Undoubtedly more cases had occurred than those found reported, but such a small number in the world's literature indicates the rarity of the occurrence.

The most comprehensive contribution on the subject was made by Hinman and Gibson.¹ They reported three cases from the literature. Wrobel's case,² a case reported by Rowlands and Nicholson,³ and another case by Sakaguchi.⁴ The description of Wrobel's case does not fully convince us that it was a true carcinoma. These authors reported a case of their own which they thought was cancer, and Ewing, Bloodgood and Ophuls took the same view, although there was some difference of opinion among other pathologists. They also cited a case reported by Stout⁵ as being a possible precancerous lesion.

Among other investigators, Coleman, Mackie and Simpson⁶ reviewed the literature and reported a case of primary carcinoma of the epididymis of embryonal origin. They found only twenty-one cases of malignant

tumor of the epididymis in the literature, including those cited by Hinman and Gibson. Fifteen of the twenty-one cases were reported as sarcoma of various kinds and six were reported as carcinoma. Two squamous cell, one basal cell, one columnar cell, and two of the adenomatous type. Besides these two reports there are a few others that were not cited by them. Blumer,⁷ a case of sarcoma of the epididymis found at autopsy, Castaño and Astraldi,⁸ a case of embryoma malignum, Comforti,⁹ a case of lympho-angiosarcoma, Thompson-Walker,¹⁰ a case of myosarcoma, Scotti Douglas,¹¹ a case of fusocellular sarcoma, in the *Transactions of St Thomas Hospital* a case of round cell sarcoma was

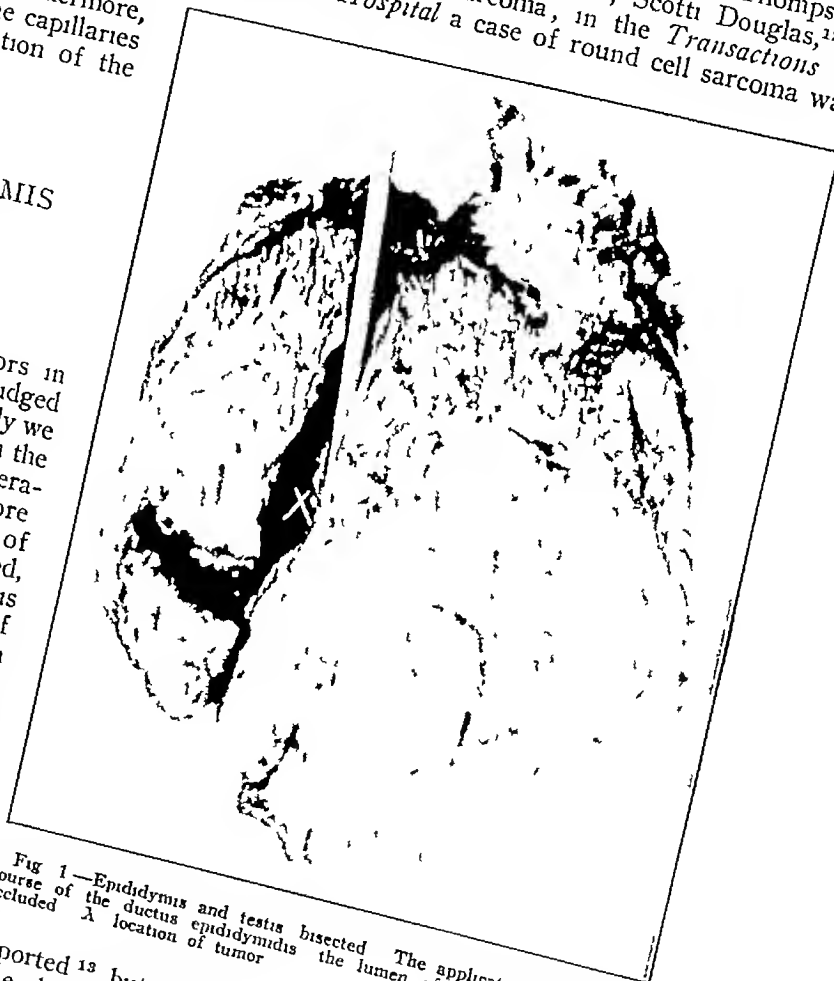

Fig 1—Epididymis and testis bisected. The applicator indicates the course of the ductus epididymidis. The lumen of the lower portion is occluded. A location of tumor.

reported¹² but the name of the author is not given. The older literature contains a few reports of sarcoma, but the diagnoses should be accepted with reservation.

REPORT OF CASE

J H Y, a white man, aged 34, admitted to the hospital, Oct 10, 1932, complained of pain in the region of the left testicle. The patient's mother died from carcinoma of the cervix at the age of 47. During the war he was thrown from the horse he was riding and fell on a fence, injuring the left testicle and prostate. He was operated on for the injury and made an uneventful recovery. He was free from any symptoms until a few days before his admission to the hospital when he began to have urethral discharges, which persisted irregularly in spite of treatments. The pain became

very severe, October 8, and on the advice of his physician he came to the hospital two days later. Physical examination showed that the left testicle was swollen to the size of an orange and was very tender to the touch. In a short while the swelling subsided and the pain eased somewhat, but it was still very tender. A tentative diagnosis of epididymitis was made, and epididymectomy and orchiectomy were done by one of us (E V J).

The gross examination of the tissues showed that the testis was atrophied but the epididymis was markedly thickened. The whole mass, including the testis and the epididymis, measured 6 cm in length, 5.5 cm in width and 2.5 cm in thickness. The epididymal portion was more than 2.5 cm wide and was thicker than the testicle portion. A white glistening fibrous nodule of irregular shape, the size of a small chestnut, was found among dark dense fibrous stroma, without capsule, at the lower third of the body of the epididymis, very near the globus minor. The nodule was on the lower part of the ductus epididymidis and was aberrant but not involving the testis, as the tunic covering it was intact. However, several fine white bands radiated from the central nodule and infiltrated into the surrounding dark stroma. The cut surface of the nodule presented a white, smooth, glistening appearance, streaked here and there with capillary hemorrhage.

Fig 2—Large epithelial cells with malignant nuclei. Reduced from a photomicrograph with a magnification of 440 diameters. Hematoxylin and eosin stain.

Under a low power objective the tissue showed numerous alveolar formations by fibrous bands, and these alveoli were filled with anaplastic epithelial cells which suggested a slight keratinization in some areas, resembling squamous cells. Some were cuboidal, containing hyperchromatic nuclei with scanty cytoplasm. Mitotic figures could be seen occasionally. The cells in the stroma were smaller and round or ovoid but also hyperchromatic and scant in cytoplasm. In certain fields the large epithelial cells infiltrated rather diffusely when they were not confined by the fibrous wall of alveoli.

The location of the tumor nodule and the total obliteration of the lower portion of the ductus epididymidis in the gross specimen and the character of the epithelial cells led us to believe that they were originated from the lining cells of the duct at the lower part of the body of the epididymis. Judging from the histologic description, the tumor in the case reported by Rowlands and Nicholson³ is very much like ours, and they called it squamous cell carcinoma. The cells look like the squamous variety in our case also, but we believe they are the metaplastic lining cells of the epididymal duct. The presence of inflammatory products in the neighborhood of the tumor nodule indicates that there had been a chronic irritation,

probably due to some damage of the epididymis, unrecognized at the time of the injury to the testicle. According to the last report, about two months after the operation, the patient was doing as well as could be expected and showed no metastasis elsewhere.

Charleston General Hospital

CASE STUDIES IN CHRONIC ARACHNOIDITIS

ELLIOTT C CUTLER, MD

AND

ROBERT ZOLLINGER, MD

BOSTON

The neurologic surgeon is forced from time to time to operate without perfect localizing signs and without full appreciation of what the pathologic condition may be. He may even be said to be forced into such action more frequently than his general surgical colleagues through threatened loss of vision or other serious and urgent symptoms. It is thus that every neurologic surgeon of experience has accumulated many cases which he must classify as "tumor suspect" or "pseudotumor" cases. Out of these groups in the last twenty years have emerged certain definite clinical entities and disorders. One of these is a symptom complex produced by blockage in the cerebrospinal pathways after the cerebrospinal fluid has escaped from the internal ventricular system. This condition is generally accepted and classified under the term "chronic arachnoiditis," though it is sometimes called "active external hydrocephalus"¹ as differentiated from that type of internal ventricular system blocking which results in the commonly recognized condition of hydrocephalus.

This condition is, however, by no means entirely new in the sense that it had not long previously been described, for in the papers written by John Hilton² and published after his lectures at the Royal College of Surgeons of England in 1860, 1861 and 1862 in the volume entitled "Rest and Pain," there is a perfect description of a patient, dying at the age of 34, whose history as well as the conditions found at a post-mortem examination would be familiar to all neurologic surgeons of today. Hilton's patient died rather suddenly after a day of severe headache and staggering gait, obviously from medullary pressure. In the history are many interesting points, for from childhood he had been subject "to headache, derangement of stomach and occasional deafness."

His pulse was usually extremely weak, irregular and slow. He had been thought to be suffering from heart disease. He had a "peculiar, restless, uneasy look of the eyes and stare, with dilated pupils."

He also carried his head peculiarly as if affected with slight stiffness in the neck. A few months before his death, while in the country, he had a severe attack of vomiting. The day he died he had great difficulty in walking, staggered badly, felt giddy, went to bed and died shortly with marked symptoms of stertorous breathing.

The autopsy showed enlarged ventricles lined with healthy tissues. "The cerebrospinal opening between the under surface of the cerebellum and the upper surface of the medulla oblongata was completely closed."

From the Department of Surgery, Lakeside Hospital, Cleveland.

2 Hilton, John. Rest and Pain, ed 3, London, George Bell & Sons, 1880.

ARACHNOIDITIS—CUTLER AND ZOLLINGER

1023

by a tolerably dense membranous structure, which formed a kind of pouch projecting downwards, and showed the direction of the fluid tension upon it to have been from above to below. The arachnoid in the neighborhood, at the base of the brain, was somewhat opaque and thicker than natural." Hilton, in writing up this case, apparently felt the need of protecting himself from criticisms of his colleagues as some neurologic surgeons feel they must do today when making the diagnosis of arachnoiditis, for he writes into the report that "this account has not been 'cooked,'" as apparently such matters were termed in his day. The description of this case of Hilton's should give courage to others to report similar cases, so that the symptom complex which relates to this condition may be more thoroughly understood and appreciated.

We believe that chronic arachnoiditis is a definite clinical entity which responds very favorably to surgical intervention. This belief is exemplified in the three cases which we present in this report. All three patients had increased intracranial pressure, marked loss of vision, and symptoms suggestive of a subtentorial block. The patients now have good vision and have remained symptom free for a period of over six years after suboccipital exploration was carried out. The cases are taken from a large group of tumor suspect cases and reported in detail as typical examples of this syndrome. Since in each case more than six years has passed since the original operation, tumor can hardly be argued as a possible etiologic factor.

REPORT OF CASES

CASE 1—History—S. S., a white boy, aged 9 years, entered the Lakeside Hospital, Oct 11, 1926, because of blindness and headaches. Nine days before admission he complained of a severe frontal headache. Close questioning showed that the

Fig. 1—Anteroposterior view of encephalogram in case 1. The third and lateral ventricles are enlarged but not displaced.

child might have had headaches for several months previously. The father stated that recently the child had been feverish and restless and had had great difficulty in emptying his bladder. The patient improved and the fever subsided following treatment by the family physician. Seven days later (two days before admission to the hospital), the boy complained that he could not see the "funny paper." At the time he was admitted to the hospital there was scarcely more than perception of light.

The family history was good. The patient had had chicken-pox at the age of 1 year and whooping cough at 5 years of age.

The boy's face was characterized by the vacant stare of blindness. There was choking of both disks to 4 diopters. A definite cracked-pot note was elicited by percussion of the skull. The reflexes were hyperactive and about equal on the two sides. There was generalized weakness of the muscles with definite ataxia to the left. The bladder was markedly distended and dribbling of urine was present. Roentgenograms of the skull gave evidence of a generalized increase in intracranial pressure. A preoperative diagnosis of a midline cerebellar tumor was made.

The more common syndrome of "pseudotumor" resulting from a generalized cysternal arachnoiditis is that of cerebellar dysfunction. Horrax⁵ reported thirty-three cases with symptomatology pointing toward a cerebellar tumor. He divided the cases into (a) acute or subacute, (b) chronic and (c) those with a preceding history of otitis media. Twenty-eight of these patients were improved or well from one to nine years after operation. Frazier⁶ classed 30 of his 1,209 cases as arachnoiditis or "pseudotumor." Twenty-two of these cases were followed at least two years, and one patient remained symptom free for twenty-five years after operation.

The diagnosis of chronic arachnoiditis is rarely made before operation. Although at operation a histopathologic change in the arachnoid membrane may be found without the discovery of a neoplasm, still the diagnosis of chronic arachnoiditis or "pseudotumor" cannot be made with certainty until a prolonged period of relief has passed. Davis and Haven⁷ believe the diagnosis of arachnoiditis should not be made but that the patients should be classed as tumor suspects and remain under close observation.

⁷ Davis I. and Haven H. A Clinicopathologic Study of the Intracranial Arachnoid Membrane. J. Nerv. & Mental Dis. 73: 129 (Feb.) 1930 (March) 1931.

Operation and Result—Under ether anesthesia the posterior fossa was explored, October 14. A cyst containing about 100 cc of clear cerebrospinal fluid under great tension was encountered below the left lobe of the cerebellum. Following removal of this fluid the tension was greatly decreased, allowing exposure and inspection of both angles. The cerebellum appeared normal, and nothing unusual was noted when the hemispheres were needled. A presumptive diagnosis of basilar arachnoiditis was made.

After an uneventful convalescence, he was discharged from the hospital on the twenty-third postoperative day.

On request he reentered the hospital, March 28, 1932, about five and a half years after the operation, for a general check-up and encephalography. His general health had been good and he had remained free of symptoms. He was doing good school work in grade 6 B. The general physical and neurologic examinations gave perfectly normal results. His vision was good, although both optic disks were a little pale and the visual fields were slightly constricted. The blood Wassermann reaction was negative.

Fig. 2—Anteroposterior view in case 2. The lateral ventricles are not displaced but the third ventricle is slightly dilated.

Encephalography was done on the day of admission. One hundred and twenty cubic centimeters of spinal fluid was removed and 90 cc of air was injected into the lumbar space. The spinal fluid Wassermann reaction was negative and the Lange curve normal. Encephalograms showed both lateral ventricles to be slightly enlarged but symmetrical and not displaced (fig. 1). The left ventricle was slightly larger than the right and the pontile cisterna was well shown. The cortical markings were definitely diminished.

CASE 2—History—E. C., an intelligent but nervous white boy, aged 9 years, was referred to the Lakeside Hospital, Nov. 4, 1925, by Dr. H. J. Gerstenberger because of vomiting and headaches. For two weeks before admission the boy complained of headaches over the left eye and about the base of the skull. Several days before admission the parents noticed that the left eye was turned slightly inward. During this time he had vomited frequently after eating. The vomiting increased during periods of constipation. Influenza was common where the boy lived and the local doctor thought the child might have had an attack at the onset of the present illness.

The boy was undernourished but well developed. He was able to walk and the Romberg test was negative. The back of the neck was very tender and stiff. There was some hypotonia in the lower extremities and very slight asymmetry in the upper extremities. Both optic disks were choked to 4 diopters and there was evidence of partial paralysis of the left sixth nerve. A diagnosis of cerebellar tumor was made.

Operation and Result—A suboccipital exploration was carried out, November 7. A distinct difference was noted between the two sides of the cerebellum. There was a darker, more translucent color beneath the dura on the left side, and the underlying lobe of the cerebellum could not be seen. A large quantity of cerebrospinal fluid spurted into the field from this area when the dura was opened because of an accumulation of fluid in the cisterna with greater extension to the left side. The lobes of the cerebellum appeared normal on inspection, palpation and needling. Nothing was found in either recess.

The immediate response to the operation was good, but cerebrospinal fluid reaccumulated. November 16, 65 cc of slightly greenish cerebrospinal fluid was aspirated and similar amounts were withdrawn on two other occasions. The patient was given a series of high voltage roentgen treatments. His general condition seemed good, although he was a little irritable and complained of headaches at times. A hernia developed in the occipital wound and he was readmitted eight months later. At operation, June 26, 1926, an endothelial-lined cavity was found which covered both cerebellar hemispheres and easily contained about 200 cc of cerebrospinal fluid. The hernia was repaired and the patient recovered rapidly. The outlines of the optic disks were indistinct but no choking was present.

In response to a request, he reentered the hospital for a neurologic examination and encephalography, March 28, 1932. His health had remained very good and his only complaint was an occasional mild headache. He had been doing good school work in the sixth grade. The only positive observations were slight haziness of the margins of the optic disks, but there was no choking. Vision was good and the visual fields were not contracted. The reflexes were not remarkable.

Ninety-five cubic centimeters of spinal fluid was withdrawn and 80 cc of air injected intermittently. Encephalograms showed the lateral ventricles to be normal in size, contour and position and the third ventricle to be slightly dilated (fig. 2).

CASE 3—History—C. S., an intelligent single white youth, aged 19 years, was admitted to the medical service of the Lakeside Hospital, Aug. 19, 1926, complaining of attacks of headaches for the past six or seven years. These attacks had become more frequent and more severe for six months until they were finally present day and night the month before admission. He obtained some relief by lying down and hanging his head over the edge of the bed. The severe headaches were accompanied by nausea, vomiting, diminution in vision and dizziness. He had noticed a peculiar buzzing in his ears, which was more marked on the right side. There had been no staggering, motor or sensory disturbances.

The positive observations were bilateral choking of the optic disks to 3 diopters and evidence of increased intracranial pressure as shown in roentgenograms of the skull. The sella turcica was quite large and the posterior clinoids were partially destroyed.

The patient was transferred to the surgical service, August 27. The history, physical examination and roentgenograms of the skull suggested a pituitary tumor or a suprasellar cyst.

Operation and Result—Because of the absence of localizing signs, a right subtemporal decompression was performed, August 28, by Dr. Allen Graham. Almost within twenty-four hours the decompression wound was tense and the intracranial pressure was probably as great as before the operation. September 25, 60 cc of spinal fluid was removed by inserting a ventricular needle through the subtemporal decompression wound. At the same time 25 cc of air was injected by lumbar puncture. A small amount of air reached both lateral ventricles, showing that the cerebrospinal pathways were not completely blocked. October 2, 40 cc of fluid was replaced by air through a ventricular needle inserted through the area of decompression. Ventriculograms showed enlarged but not

distorted lateral ventricles. A cerebellar exploration was carried out, November 5. It was thought that the pia was a little thickened, but the exploration was otherwise entirely negative.

The postoperative course was uneventful and the patient was discharged from the hospital, November 23.

By request he reentered the hospital, March 4, 1932, almost five and a half years after the suboccipital exploration, for a check-up and encephalography. He had recovered completely and remained symptom free. Vision in both eyes was good and the optic disks were normal in appearance. The neurologic examination was negative.

Examination of the spinal fluid showed 3 cells per cubic millimeter and a negative Pandy reaction. The Wassermann reaction was negative. The total protein was 213 mg per hundred cubic centimeters. One hundred and seventy-five cubic centimeters of spinal fluid was removed and 150 cc. of air injected. Encephalography showed the ventricles to be slightly enlarged but normal in contour and position (fig 3). The air was distributed equally in the cortical pathways over the two hemispheres.

Fig 3—Anteroposterior view in case 3, showing moderately dilated but not displaced ventricles

COMMENT

We believe that these patients have remained symptom free for a sufficient number of years to make the diagnosis of intracranial tumor unlikely. Furthermore, by encephalography the ventricles were found to be symmetrical in outline and position. This finding gives further conclusive evidence against the presence of tumor, which in a period of more than six years would have produced some distortion of the ventricular system. The accumulation of cerebrospinal fluid in the posterior fossa probably results from partial obstruction by scar tissue in the subarachnoid channels at the level of the tentorium. Experimentally, Dandy⁸ has produced hydrocephalus by causing adhesions about the incisura tentorii which blocked the free flow of cerebrospinal fluid upward from the posterior fossa. Thus, he

believes, limits the absorption of the cerebrospinal fluid to one fifth of the total arachnoid space. Perhaps a low-grade infection, such as influenza, might produce adhesions in the cisterna of these patients and a sub-tentorial block with the resulting accumulation of cerebrospinal fluid in the posterior fossa. A sub-occipital decompression gives relief by creating additional space during the periods of excessive formation and accumulation of the cerebrospinal fluid, and permits the gradual but continuous passage of the fluid so that in time of lessened secretion the excess accumulated passes by the blocked area and no great pressure is exerted. Thus, a suboccipital decompression in such cases acts merely as a safety valve.

SUMMARY

In three cases of "pseudotumor" or chronic arachnoiditis in which there were symptoms of highly increased intracranial pressure, blindness or poor vision, and evidence of cerebellar dysfunction, the patients have remained symptom free with good vision for more than six years after suboccipital decompression. There is no evidence of intracranial tumor, as shown in recent encephalograms.

Clinical Notes, Suggestions and New Instruments

HYPOTHYROIDISM ASSOCIATED WITH CARDIAC ENLARGEMENT (MYXEDEMA HEART) AND AURICULAR FIBRILLATION

JOHN E. WALKER, M.D., OPELIKA, ALA.

Cardiac enlargement associated with hypothyroidism was first described by Zondek.¹ Ayman, Rosenblum, and Falcon-Lesses² recently reviewed the subject, collecting reports of twenty-two cases from the literature and reporting two cases of their own. Gotten³ has since reported another case. Cardiac insufficiency was present in some of these patients. The administration of thyroid Digitalis therapy was often given without benefit before the proper diagnosis had been made. The striking result produced by thyroid in this condition is paralleled only by the effect of vitamin B on the cardiac enlargement in beriberi, as described by Aalsmeer⁴ and others. This paper will describe another case of hypothyroidism with cardiac enlargement, apparently the twenty-sixth to be reported. The patient also emphasizes the fact that marked hypothyroidism may occur in slender individuals without the typical appearance of myxedema. Further, auricular fibrillation was present. Although auricular fibrillation is a frequent complication of hyperthyroidism, this is the first example, to my knowledge, of its association with hypothyroidism.

REPORT OF CASE

History—The patient was a white man, aged 39, a machinist, seen, May 4, 1932, complaining of aching pains in the arms and legs and shortness of breath. He had been married twelve years, there were two children living and well, his wife had had no miscarriages. The family history was otherwise unimportant. He had never had typhoid, rheumatic fever, dysentery or venereal disease. He had malaria in 1912. In 1918 he enlisted in the army, passing the physical examination without com-

ment His health was good during his army service except for influenza in France, which required hospitalization for thirty days At the time of his routine physical examination incident to discharge from the army in 1919 he was told by the medical officer that his pulse was irregular and that he needed hospitalization for further study He refused to enter a hospital, saying that he had no complaint, and his request for immediate discharge was granted In 1921 he was refused for life insurance on account of irregular pulse Since that

Fig 1—Measurements of heart A, before thyroid therapy, B, after thyroid had been taken for five months

date he has been aware of irregular pulse all the time, determined by feeling of it There has been no subjective consciousness of an irregular heart He had another attack of influenza four years before the time of examination

About 6 years before, he noted that he did not perspire On hot days his fellow workers would be drenched with perspiration, while his own skin remained perfectly dry He had also been cold natured These complaints were brought out by leading questions, and the patient had attached no particular significance to them He suffered from constipation for years

He considered that his present illness began two years before, when he broke down physically following a period of several weeks during which he attempted to work from fifteen to eighteen hours a day He became weak and suffered from dizziness and shortness of breath He had not been able to work since, though he had been up and about most of the time During the past two years he had suffered almost constantly from deep aching pains in the arms and legs All of his teeth were pulled in the effort to correct this aching, which had been diagnosed as arthritis A year before, he entered a hospital, where a roentgenogram showed enlargement of the heart He was given digitalis without benefit and left the

Fig 2—Condition before thyroid therapy auricular fibrillation, T waves almost iso-electric

hospital after two weeks He had been forgetful His feet had been moderately swollen from time to time

Examination—The patient was slender, 70½ inches (178 cm) tall and weighing 150 pounds (68 Kg) The skin was of a yellowish, pasty color There was slight puffiness of the lower lids There was a raised erythematous desquamating area about 4 by 8 cm on the extensor surface of the left forearm There was no edema The axillae were dry

The pulse was totally irregular in force and rhythm, with a rate of 60, and no pulse deficit The blood pressure was

approximately 140 systolic, 80 diastolic The apex impulse was not visible nor palpable The area of relative cardiac dulness was enlarged There were no heart murmurs

A teleroentgenogram of the heart showed transverse enlargement (fig 1A) The measurements were midline to right border, 5.4 cm, to left, 11.5 cm, transverse diameter, 16.9 cm, internal diameter of the thorax, 28.3 cm ($16.9 - 28.3 = 60$ per cent), length, 17.9 cm, great vessels, 5.2 cm The electrocardiogram showed auricular fibrillation, rate 54 The T waves were almost iso-electric (fig 2)

Fluoroscopic examination of the gastro-intestinal tract was negative The gastric contents after an Ewald meal contained no free hydrochloric acid on two examinations There was no occult blood in the stool The urine contained a trace of albumin, no bile, urobilinogen, sugar or casts, the specific gravity was 1.017 The icterus index of the blood serum was 6 The Wassermann and Kahn tests were negative

The basal metabolism was minus 41 per cent

The red blood count was 3.9 million, hemoglobin, 73 per cent, white blood cells, 4,500, neutrophils, 54 per cent, eosinophils, 4 per cent, basophils, 1 per cent, lymphocytes, 36 per cent, monocytes, 5 per cent The red blood cells appeared normal on smear

Course—The patient was given 1 gram (0.065 Gm) of thyroid, U S P, a day, the daily dosage being increased 1 gram each week until he was taking 4 grains (0.26 Gm) a day This dose was maintained until the end of the fifth week The basal metabolism was minus 26, minus 22 and minus 5 per cent at the end of the second, third and fifth weeks, respectively Since then the basal metabolism has varied between minus 9 and plus 3 per cent on a maintenance

Fig 3—Condition after patient had been taking thyroid for five months T waves much more pronounced, auricular fibrillation still present

dose of from 2 to 2½ grains (0.13 to 0.16 Gm) of thyroid daily The patient, in addition, has received pills of ferrous carbonate and dilute hydrochloric acid, and has been instructed to eat a diet containing meat, green vegetables, milk and eggs

At the end of three weeks there was an almost complete disappearance of the yellow pallor, and the skin lesion on his left forearm had healed At the end of the fourth week he had begun to perspire normally The troublesome aching pains also disappeared His weight decreased to 138 pounds (62.6 Kg) after five weeks of treatment but has since increased to 145 pounds (65.8 Kg) Throughout the whole time of treatment the patient was ambulant, being seen only at the office After three months he resumed his regular occupation and has worked eleven hours a day for five days a week since that time (The total period of observation has been six months)

Thyroid therapy had no effect on the auricular fibrillation, although the T waves became very much more prominent in the electrocardiogram (fig 3) No effort was at first made to treat this arrhythmia, since it seemed desirable to ascertain whether it would not disappear under thyroid therapy Recently quinidine sulphate in doses up to 15 grains (1 Gm) a day has caused no change I hesitate to give this ambulant patient full doses of quinidine, although this is recommended by Weisman⁵

A teleroentgenogram showing the marked diminution in the size of the heart after five months' observation is shown in figure 1B The measurements are midline to right border, 3.8 cm, to left, 9.6 cm, transverse diameter, 13.4, internal diameter of thorax, 28.5 cm ($13.4 - 28.5 = 47$ per cent), length, 14.8 cm, great vessels, 4.7 cm

5 Weisman S A Auricular Fibrillation Ambulant Treatment with Quinidine, Arch Int Med 49 728 (May) 1932

SUMMARY AND CONCLUSIONS

An additional case of hypothyroidism associated with cardiac enlargement ("myxedema heart") was observed. The heart returned to normal size under thyroid medication. The heart condition was complicated by the presence of auricular fibrillation, on which thyroid had no effect. It appears entirely logical to consider that the auricular fibrillation was caused by the hypothyroidism, although it cannot be disproved that the arrhythmia was an independent condition of unknown etiology.

The slenderness of this patient emphasizes the fact that hypothyroidism is not necessarily associated with obesity. Other than slight puffiness of the lower lids and a yellowish pallor, his appearance or demeanor in no way suggested hypothyroidism. A typical history of hypothyroidism was brought out only by leading questions.

ELECTROCARDIOGRAPHIC OBSERVATION DURING
CARDIAC PAIN

LOUIS FAUGERES BISHOP, M.D. AND LOUIS FAUGERES
BISHOP, JR., M.D., NEW YORK

The opportunity of taking an electrocardiogram during an attack of cardiac pain occurs rather rarely in private practice. We were fortunate enough, recently, to have this experience in our office. The patient was a man, aged 48, who had had moderately severe precordial pain for fourteen hours previous to our observation. This pain was practically continuous and radiated to his left arm, as far as the elbow. It was unaccompanied by any other subjective symptoms. As he had been unable to obtain any symptomatic relief and suspecting the possibility of this being an attack of angina, he sought medical advice.

A history was obtained of his having had slight pain on exertion, particularly when walking, for the past three months. Otherwise he had been always well.

The physical examination was entirely negative except for a hypertension, the systolic blood pressure being 190 and the diastolic 100. Whether this was an accompaniment of his anginal attack or a preexisting condition it was impossible to say at the time. No leukocytosis was present. The temperature was normal. Other laboratory examinations, including a six-foot roentgenogram, urinalysis and a Wassermann test, gave no significant results.

Fig 1—T wave iso-electric in all leads in record obtained June 17, 1932. Occasional ventricular extrasystole.

The first electrocardiographic examination was made on June 17, 1932 during this anginal attack. The significant findings were the fact that the T wave was iso-electric in all leads. In addition there was an occasional ventricular extrasystole present (fig 1).

Following this examination the patient was immediately put to bed for a period of rest. His pain gradually disappeared. The blood pressure fell to 130 systolic 80 diastolic. No other physical signs or fever developed. No medication was given except mild sedatives. June 27 a second electrocardiogram was taken which showed further changes in the T wave, consisting of inversion in leads 1 and 2 (fig 2).

Although the duration and severity of this attack of pain led to the probable diagnosis of a coronary thrombosis, it was not until the second graph was taken that we were able entirely to confirm the characteristic sequence of events representing the progression of pathologic events that had taken place.

As it is an exceedingly difficult matter to decide whether infarction of the heart has taken place or not during an attack of pain, it seems to us important that whenever an opportunity affords, attacks of cardiac pain, either of brief or of prolonged duration, should be studied electrocardiographically. The electrocardiogram actually taken during the paroxysm of pain in this case did show early changes in the T wave.

Fig 2—T wave inverted in leads 1 and 2 in record obtained June 27, 1932.

It is well known, as has been shown by Parkinson and Bedford,¹ Feil and Siegel,² and others, that even during short paroxysms of pain there may be definite and transitory changes in the ventricular deflections of the electrocardiogram. It is particularly significant that both transient pain and true infarction can affect the electrocardiogram in a similar manner. The mechanism underlying these changes may be essentially the same.

This case seems to us important because in the first place an opportunity was afforded to electrocardiograph a patient during an attack of actual cardiac pain in office practice. At the time of the attack, early changes in the T wave were noted. At a later date the electrocardiographic observations were those often seen in cardiac infarction. A diagnosis of cardiac infarction, although suspected clinically, could at a later date be confirmed, electrocardiographically.

121 East Sixtieth Street

HYPERPYREXIA WITH CORONARY THROMBOSIS

JOHN H. FOSTER, M.D., WATERBURY, CONN.

Fever and leukocytosis appearing shortly after the onset of symptoms are regarded as important points in the diagnosis of coronary thrombosis. The rise in temperature is quite constant, usually running from 99.6 to 102 or 103 F for a few days to a week and is apparently due to absorption of the decomposition products from the necrosing muscle in the infarct area.

The unusually high fever in the case of coronary thrombosis recorded here seems to make it worth reporting.

F. L. S., an executive in a local foundry, was 44 years of age and had apparently been in excellent health. He had always been athletic, full of abundant energy and kept up his gymnastics, volley ball, and golf throughout the year. He was a rather heavy smoker and moderate user of alcoholic liquors. He had passed several examinations for life insurance during recent years. I examined him in 1930 for one company and found nothing definitely wrong. On a later check up roentgenograms of his teeth were negative and the blood Wassermann reaction was negative, but he did have boggy red tonsils.

² Feil Harold and Siegel M. L. Electrocardiographic Changes During Attacks of Angina Pectoris. *Am J M Sc* 175: 255-260 (Feb) 1928.

Business worries had been extreme and he had not taken a vacation the past year. During the week before the onset of his illness he had played through a local golf tournament. The day preceding he had felt substernal pain briefly during his match, which had been relieved by a short rest, but he slept well that night.

Fig 1—Clinical course, showing rise of temperature to 107.2 F

On the morning of Sept 24, 1932, he complained to one of his associates of a tightness in his chest. About 9:45 a.m., while alone on the third floor, he called to the telephone operator, who went to him as quickly as she could. He staggered across to the elevator and collapsed, complaining of terrible pain in his chest.

I saw him about fifteen minutes later. He was conscious, but was cold, clammy, pulseless and gray. The heart sounds

were almost inaudible. The pain was apparently terrific all through the epigastrium, chest, neck and shoulders.

Morphine, one-half grain (0.03 Gm), was given at once and repeated twice at about fifteen minute intervals before the pain was finally eased. Epinephrine, 0.5 cc, before the last

was unable to void urine and required catheterization till the end. Perspiration was profuse.

The heart sounds were very distant for the first hour but became stronger and more rapid. The second sound was replaced by a systolic murmur and there was gallop rhythm. No definite pericardial friction sounds were heard. The blood pressure varied, as is noted in the temperature chart, from being unobtainable at first to 130 systolic, 80 diastolic, the first day. The systolic pressure gradually dropped to 80 and to

Fig 3—Section of coronary artery showing sclerosis, arteritis and thrombus

60 during the last two days. The lungs remained clear and there was only slight abdominal distention.

The leukocyte count was 20,300, with 85 per cent polymorphonuclears on the 25th and 16,000 on the 27th. The urine was concentrated but otherwise normal.

With the rise in temperature and dehydration he became irrational and very restless. Toward the end he became almost maniacal, requiring restraint and narcotics. Dextrose intravenously, 100 cc of a 50 per cent solution, was given twice daily, and 1,000 cc of Ringer's solution by hypodermoclysis helped only partially. Morphine, one-fourth grain (16 mg), with or without atropine, one-one hundred and fiftieth grain (0.4 mg), gave most relief and was administered every three to six hours. The oxygen tent seemed only to increase the restlessness.

An electrocardiogram (fig 2A) taken ten hours after the onset showed a heart rate of 76 per minute, with sinus rhythm. The QRS wave in lead 1 was almost iso-electric, showing only a slight notching, with a high ST. Axis deviation was plus 55 degrees.

The electrocardiogram taken on the 26th (fig 2B) showed a rate of 120. The QRS in lead 1 was wider. The ST wave taken was higher, but the T wave was upright. QRS in leads 2 and 3 was slurred, and T_2 was now inverted. Neither showed the typical changes of coronary thrombosis, both showed signs of a badly damaged myocardium.

Partial autopsy fifteen hours after death and after embalming showed a heart of normal size. There was an area of fibrinous exudate on the posterior surface of the heart and a hemorrhagic discoloration of the posterior pericardial sac but no increase of pericardial fluid. The whole left ventricle was dark and soft. Sections showed the ventricular muscle to be hemorrhagic and flabby, and in places near the apex questionable abscess formation. The surface arteries were bluish streaked and on section were hard and cartilaginous throughout. The larger portions were irregular and felt calcareous. About 1 cm from the origin of the left coronary artery was a thrombus which appeared hemorrhagic on the surface and which was demonstrated on section. A cross section (fig 3) prepared by Dr J O Collins of the Waterbury Hospital showed the advanced sclerosis of the artery, signs of arteritis in some areas, and a part of the clot which caused the occlusion.

Fig 2—Signs of damaged myocardium A, ten hours after onset, B, fifty-four hours after onset

administration of morphine and again after about fifteen minutes seemed to increase the strength of his pulse and heart sounds. He slept quietly for three hours, when he was removed by ambulance to his home.

The temperature chart (fig 1) shows graphically the course during the next four days. The severe pain did not return but he frequently complained of a feeling of substernal pressure, which was worse when the bladder was distended. He

GALVANIC BURN—HOLLANDER ET AL

1029

Reports of coronary thrombosis in its various aspects are frequent, but a survey of the literature has failed to disclose any case with such a degree of hyperpyrexia.

103 North Main Street

GALVANIC BURNS OF THE TONGUE

LESTER HOLLANDER, M.D., LEO SHONFIELD, D.D.S., PITTSBURGH AND ABRAHAM FISHER, M.D., MCKEESPORT, PA.

That galvanic currents generated by dissimilar metals used for the purpose of dental fillings, crowns and bridgework may cause lesions of the mucous membrane of the oral cavity has been noted previously by Fitzwilliams,¹ Lain² and Hollander.³ The following report adds another clear-cut demonstration of that contention.

REPORT OF CASE

History—G. R., a married man, aged 40, white, an electric welder, referred to the Pittsburgh Skin and Cancer Foundation, July 2, 1932, by Dr. P. J. Zeedick, presented six faceted lesions

There were no other dental restorations in his mouth. The crowns had been inserted sixteen months before and the bridge-work twelve months before. Shortly after the bridge was installed, the lesions described made their first appearance on the tongue and had since grown progressively worse. The patient complained of a metallic taste, a burning, and a sensation of thickness of the tongue. Smoking, chewing of tobacco or anything that caused an increased flow of saliva aggravated the subjective symptoms.

Fig 1—Clinical appearance of the lesions

on the margin and tip of the anterior third of the tongue. Although this entire area of the tongue was swollen and reddened, each lesion was distinct and separate and conformed in shape to the lingual surfaces of the upper anterior teeth. The center of each of these six lesions was depressed, and the borders were raised above the surrounding inflamed mucous membrane covering of the tongue. The lesions themselves were covered entirely by a white discoloration, which felt thick and rough and was so firmly attached that it could not be removed. This portion of the tongue rested against certain dental restorations, which consisted of three crowns and a small fixed bridge.

Fig 2—Gold crowns and bridgework

The upper right lateral, the upper right cuspid and the upper right first bicuspid were crowned with hollow metal two piece carat gold. The upper left lateral incisor had a hollow metal two piece 22 carat gold crown to which the upper left lateral incisor, in the form of a porcelain pin facing, was soldered. This bridge had also a lingual rest extending into the gingival third of the natural left central incisor. The porcelain pin facing and the lingual rest were backed with 24 carat gold and soldered to the gold crown with 18 (?) carat gold solder.

Fig 3—Histologic structure of one of the lesions. The marked acanthosis and lymphatic cell infiltration of the corium may be noted.

A clinical diagnosis of leukoplakia linguae and chronic glossitis was made.

Course of the Disease and Treatment—July 7, 1932, the largest lesion was removed for microscopic study. July 13, all restorations were removed. July 15, the tongue showed a marked improvement, the lesions became flatter and most of the inflammation and all the subjective symptoms disappeared. On account of the presence of periapical infection, the upper right lateral, the upper right cuspid and the upper right first bicuspid were extracted. By July 21, the lesions had disappeared entirely.

Fig 4—Mouth after dental restorations and infected teeth had been removed.

The histologic structure showed changes both in the superficial and in the deeper layers of the lingual mucosa. This consisted of a hyperkeratosis, an intense acanthosis with widening and deep proliferation of the interpapillary pegs, and a marked lymphocytic infiltration of the papillary layer. The blood vessels appeared dilated. Thus the histologic structure confirmed the clinical diagnosis of leukoplakia and chronic inflammation of the tongue.

In order that the possibility of a hypersensitivity of the patient to gold could be excluded, a patch test was carried out, leaving the removed gold in apposition with the skin for a period of one week. This procedure caused no perceptible reaction.

Fig 5—Healed condition of the tongue

COMMENT

The history, clinical appearance before and after the removal of the crowns and bridgework and photomicrographs of one of the lesions are submitted to substantiate further the contention that galvanic burns cause pathologic lesions in the oral mucosa.

TORULA MENINGO ENCEPHALITIS

JAMES B ROGERS, M D AND FRANKLIN JELSMA, M D
LOUISVILLE, KY

This case of torula meningo-encephalitis is reported as a matter of record and to call attention to the recognition of this condition, rather than because of some unusual feature of the case. The clinical course is fairly representative of torula infection of the central nervous system.

The literature up to 1929 has been reviewed thoroughly by Stone and Sturdivant.¹ The differential points between torula

Fig 1—Section through leptomeninges and cortex in area of infection, showing a portion of an artery with *Torula histolytica* present in large numbers in the pia. Reduced from a photomicrograph with a magnification of 990 diameters.

infection, oidiomycosis and coccidioidal granuloma were considered in detail by Stoddard and Cutler.²

REPORT OF CASE

G. G., aged 47, a telegrapher, first observed Feb 10, 1930, was found lying unconscious on the floor by his wife, three

weeks previously, just before the usual time to depart for work. Prior to this time his health had been good. After a short time he regained consciousness. There was a total amnesia for events immediately preceding the unconscious state. The patient remained in bed for three weeks at home, during which time he complained of severe headache, a defective memory and occasional vomiting. He seemed entirely unconcerned about his condition. His vision became decidedly impaired. Three other unconscious spells occurred, each lasting from two to three minutes, and all free from convulsive manifestations. At times dizziness and incoordination became so pronounced that he dared not walk.

The past history was irrelevant.

On neurologic examination the patient appeared quite euphoric and uncooperative. The sense of smell was diminished bilaterally. There were 5 diopters, choking of both disks and numerous hemorrhages in the right fundus. Visual fields could not be determined because of lack of cooperation of the patient. The left seventh nerve showed a supranuclear paralysis. Marked mental deterioration, memory changes and euphoria were present. No aphasic symptoms or sensory changes could be demonstrated. There was a spasticity and weakness of the left extremities.

Dizziness, incoordination and a tendency to fall to the left were present. The Romberg sign was positive. Adiado-

Fig 2—Section through leptomeninges, showing *Torula histolytica* in large numbers. Reduced from a photomicrograph with a magnification of 1,375 diameters.

kinesia was marked in the right upper extremity. There was a coarse, well sustained nystagmus of both eyes.

Abdominal and cremasteric reflexes were absent on the left. The Babinski, Gordon and Oppenheim reflexes were not present. The blood and urine observations were normal. Spinal fluid and blood Wassermann reactions were negative.

A tentative diagnosis was made of a right frontal lobe lesion, and the patient was removed to the hospital, February 11, for diagnostic study and treatment. He continued to complain of severe right frontal pain. His general condition remained about the same. Because of the possibility of an intracerebral hemorrhage and the atypical history of neoplasm, a burr hole was placed in the postfrontal area and the brain explored with a needle. At a depth of approximately 3 cm, definite resistance was encountered. At a depth of approximately 4 cm a dark brown fluid escaped from the needle. About 12 cc of the fluid was drained, which did not yield organisms on culture. Primary smears were reported negative for organisms. Examination of the fluid showed large amounts of bilirubin and biliverdin. It was considered typical of laked blood. The anterior horn of the ventricle was punctured, the ventricular fluid was replaced with air and stereoradiographs were taken.

Ventriculograms showed ventricles of normal contour and location. The day after the operation, the headache subsided. Improvement continued and the patient left the hospital,

PRELIMINARY REPORTS OF THE COUNCIL
THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
PRELIMINARY REPORT
PAUL NICHOLAS LEECH, Secretary

DILAUDID

In the past few months a new narcotic drug, dihydro-morphinone hydrochloride, has been introduced for clinical use in this country under the proprietary name "Dilaudid." It is marketed by Bilhuber-Knoll Corp., Jersey City. The drug has been used in Europe for some years, having been patented in 1923. The first paper on its pharmacologic action appeared in 1926 together with a clinical report by Krehl. Since that time numerous articles on its action have been published, at the present time the bibliography of the product numbers some two hundred titles.

Briefly stated, the drug is closely allied both chemically and pharmacologically to morphine, having the analgesic property of morphine as well as its action on the respiratory system. Its action on the intestine is probably less marked than is that of morphine. It is more toxic than morphine and is clinically effective in doses which are considerably smaller than are necessary with that alkaloid.

A most important point to be considered in connection with its use, however, is whether or not its administration is followed by a condition of euphoria which might lead to addiction such as is so common with morphine. It is largely in connection with the latter property that the superiority of Dilaudid over morphine is being urged, it becomes therefore a matter of great importance to ascertain whether this claim to superiority is merited.

The drug was brought to the attention of American clinicians largely by a statement by Alvarez of the Mayo Clinic, published in the *Proceedings of the Staff Meetings* in August, 1932. In discussing the euphoric action of Dilaudid, Alvarez stated that so far as he knew no one had as yet become habituated to its use. Unfortunately, this statement was unwarranted because already at that time a number of cases of addiction to Dilaudid had been reported in the literature. More than once warnings and to the need of caution until more was known of the possible dangers of the drug.

Shortly after Alvarez's remarks were made at the staff meeting, a similar statement appeared in the Associated Press news from "Science Service." This resulted in wide publicity, as it was copied more or less accurately by the press of the country. A few of these statements follow.

From *Collier's* Dec 10, 1932 "Keeping Up with the World," by Freling Foster
A new drug five times as potent as morphine has recently been brought to America from Germany. It is particularly useful in the last stages of cancer because it virtually relieves all pain and permits the patient to be up and working.

From the *Literary Digest* Dec 17, 1932
Five Times as Powerful as Morphine but Harmless

A NEW pain relieving drug which is about five times as potent as morphine without the latter's habit forming quality, was described by Dr. Walter C. Alvarez of the Mayo Clinic at Rochester, Minnesota recently.

To quote a mail report of Science Service (Washington)
"The new drug is Dihydro-morphinone hydrochloride. It was developed in Germany in 1926 by the Knoll laboratories but it is only now being brought to the attention of physicians in this country. It is particularly useful for cases of cancer that cannot be operated on. It gives more relief from pain than morphine and prolongs the useful life of the patient who can be up and working while taking this drug. Of course it is not a cure but it does help the patient by relieving the pain and other symptoms of the last stages of the disease. Dr. Alvarez also suggested that it might be used in treating morphine addiction. Occasionally it may be helpful in the treatment of morphinism through its power to relieve distress while the patient is getting a grip on himself."

The drug does not seem to be dangerous does not produce the pleasurable sensations of morphine and consequently is not habit forming. In a few persons it has some of the troublesome effect but to compensate for this it has none of the troublesome effect on the intestines. The new analgesic is made from morphine hydrochloride with the help of a catalytic agent which causes it to combine with water.

February 22 About three weeks later he was able to return to work.

There were no further disturbances until almost two years later (Feb 7, 1932). The patient had gone to work as usual, feeling well. About midnight, a severe right frontal headache and vomiting incapacitated him. He was removed to the hospital, February 9. The physical examination at this time revealed a good pulse of 80 per minute. The blood pressure was 120 systolic, 80 diastolic. The temperature was 98.8 and respirations were 20. He was dehydrated. There was a definite weakness of both left extremities. The lungs, heart and abdomen were essentially normal. Neurologic examination showed 1 diopter of swelling of both disks, a supranuclear type of paralysis of the left seventh nerve, weakness of the left extremities with hyperactive deep reflexes, and a positive Kernig sign. There was 250 mm of spinal fluid pressure. The fluid was clear, yet a microscopic examination revealed 127 erythrocytes per cubic millimeter, 51 leukocytes and 210 yeast cells. The total protein was 45 mg per hundred cubic centimeters. Globulin and colloidal gold and Wassermann tests were negative. The urine and blood were normal. Roentgenograms of the chest were essentially negative.

At the hospital, the patient complained bitterly of a right frontal headache. The temperature was 99.4. The pulse was 80 and respirations were 20. February 10, the patient had a convulsion, which began on the left side and became generalized. He remained unconscious for twenty-five minutes. February 11, 50 cc. of ventricular fluid was withdrawn and replaced with 20 cc. of air. These ventriculograms showed the lateral ventricles to be of normal position and contour except for an irregular collection of air in the right parietal lobe that seemed to connect with the right ventricle. This was interpreted as a small cyst that had ruptured into the ventricle. Various anodynes and hypnotics were used. Sodium iodide, 10 cc of a 10 per cent solution, was given intravenously on three successive days. Spinal puncture would relieve the headaches to some extent, but the patient's condition continued to grow worse. February 14, about 2 ounces (60 cc.) of dark sanguineous fluid was drained by needle from the parietal region. A section was taken for study, including leptomeninges and cortex. Convulsions increased, the patient became irrational and died, February 21. A necropsy was refused.

The microscopic sections of tissue specimen showed a proliferation of connective tissue cells in the pia, a few lymphocytes and numerous torulae. The protoplasm of the organisms stained pink with eosin and contained a mass of irregular dark granules. Budding forms were common. The torulae varied from 2 to 12 microns in diameter. Many were surrounded by a clear zone. There were no polymorphonuclear leukocytes in the tissue.

COMMENT

In this case marked temperature increase was never a prominent symptom, and during the first two years of infection the condition remained localized, only once giving symptoms of a focal nature. These symptoms were due apparently to an accumulation of fluid in the postfrontal region. When the fluid was removed, the symptoms promptly disappeared. Two years elapsed before progress of the infection was sufficient to give further symptoms, which, at this time, appeared as meningeal as well as focal cerebral symptoms. The infection had slowly progressed and invaded the meninges when the organism was found in the spinal fluid.

The World Beyond the Unaided Eye—Leeuwenhoek was not without honor during his lifetime. Scientists and nobility came to Delft to see this man of the microscopic world. Peter the Great of Russia, Queen Mary of William and Mary, Frederick I of Prussia and others stopped in Delft to call on Leeuwenhoek. Like the public of today these rulers of the seventeenth century were impressed with the scientific developments of their day. They were curious to know what lies in the world beyond the unaided eye of man. Leeuwenhoek made many microscopes the exact number is not known although he left 247 not only with lenses but usually with objects in place. He also left 172 plates with one lens in each or a total of 419 lenses.—Fred E B Antony Van Leeuwenhoek on the Three-Hundredth Anniversary of His Birth *J. Bacteriol* 25 1 (Jan) 1933

From the *Montgomery (Ala.) Advertiser*, Dec 18, 1932

"AN IMPORTANT NEW DRUG"

"Di hydro morphinone hydrochlorid

"That's it The Mayo Clinic at Rochester developed it, the word and the drug, for it means a drug, a pain relieving drug, five times as potent as morphine, as harmless as water and with no habit forming qualities

"The medical journals say it is particularly useful in the operation of cases where other drugs seem to offer no relief from pain. Unlike morphine, there are no pleasurable sensations to its use, however, and if the doctors reckon correctly its use may go far toward curing addicts of the morphine habit"

As a result of this wide publicity, many inquiries were received by the Association and by the Council. These came not only from physicians but also from laymen. Persons who were suffering from pain but feared to take morphine were especially interested, as now they were promised a drug which was reputed to be "harmless as water", and even in cases of advanced cancer it was said that it would prolong their lives and permit them to return to work once more.

Realizing the importance of furnishing accurate information in this case both to the profession and to the laity, the Council asked Dr. Nathan B. Eddy of the Department of Pharmacology of the University of Michigan to make a report to the Council on the general status of the alkaloid. It seemed especially fitting that Dr. Eddy should be asked to report on this question because, as is well known, Dr. Eddy is engaged on a study of the action of possible substitutes for morphine under funds supplied by the Rockefeller Foundation to the Drug Addiction Committee of the National Research Council.

Dr. Eddy's report on the literature and on the results of his experiments with Dilaudid appears below. The report has been reviewed by the Council and is published with its approval and with its thanks to Dr. Eddy for the preparation of the report.

The Council has postponed for a reasonable length of time the consideration of Dilaudid with the view of determining its eligibility for inclusion in New and Nonofficial Remedies in order to give the manufacturer opportunity to submit it and to revise the advertising in conformity with the available evidence.

DILAUDID (DIHYDROMORPHINONE HYDROCHLORIDE)

NATHAN B. EDDY
ANN ARBOR, MICH.

Dilaudid (di-hydromorphinone hydrochloride) was first described in the German patent literature of 1923,¹ and after a very brief pharmacologic study² was given to a number of clinics for trial, the first report of its use appearing in 1926.³ Since then, the German clinical literature has contained many references to it, and recently two papers on the subject have appeared in English journals, so that at the present writing a complete bibliography would number nearly 200 titles. As reported in the *Lancet*,⁴ the Committee of Experts, appointed in May, 1931, by the Council of the League of Nations to consider the advantages and disadvantages of heroin (diacetylmorphine) and the possibility of substituting some other substance for it, briefly summarized the situation in regard to dilaudid as follows: "For the relief of pain in patients in whom it is undesirable to act on the bowels, heroin is better than morphine but dilaudid offers the same advantages. Dilaudid has a slightly weaker effect on the respiratory center than heroin, it has the same analgesic effect as heroin, both drugs have little effect on the alimentary canal. The euphoric effects of dilaudid are weaker than both morphine and heroin as gaged by withdrawal symptoms."

Chemically, dilaudid is dihydromorphinone hydrochloride. Its relationship to morphine is shown by their structural formulas. It differs from morphine in two respects: replacement of one of the hydroxyls by a ketonic oxygen, and removal of an adjacent double bond by hydrogenation. The substance is prepared by hydrogenation of morphine in warm strongly acid solution in the presence of a large excess of palladium or

platinum catalyst. It is a white crystalline powder readily soluble in water, it contains 88.7 per cent of alkaloidal base.

REVIEW OF CLINICAL EXPERIENCE

Dilaudid has been used by all the usual modes of administration—oral, rectal, subcutaneous and intravenous—and by all the routes the most commonly employed dosage has been from 2 to 25 mg. Some authors have found larger doses necessary, and a few have reported results with less. Nearly all of them, however, have commented on the early development of effects, stating that relief of pain, for example, was accomplished within from ten to fifteen minutes, whatever the mode of administration.

Structural formulas

Reported dosages have ranged from 1 to 75 mg for a single administration, with 25 mg as the maximum for twenty-four hours. Freundlich⁵ gave 5 mg as the usual preanesthetic dose, while Ditttrich⁶ found 25 mg satisfactory for the same purpose. Lullies,⁷ reporting the use of dilaudid in more than 1,000 surgical cases, said that 2 mg was usually not sufficient but that 3 or 4 mg was given subcutaneously or from 25 to 5 mg by rectum. Simenauer and Pulfer⁸ also reported that from 2 to 3 mg had a negligible analgesic action, that 4 mg decreased and abolished pain, but that two doses of 4 mg was the highest daily dosage they had used. Grage,⁹ on the other hand, used 2 mg orally or 25 mg subcutaneously in tabetic crises and said that 1 mg was sometimes sufficient.

Krehl,³ Paulsen,¹⁰ Schwarz,¹¹ Crohn,¹² Klemperer,¹³ Markowicz,¹⁴ Paepfer,¹⁵ and others reported favorably on the use of dilaudid in the treatment of cough, especially in tuberculosis. They gave from 125 to 75 mg and repeated the larger doses three times or the smallest amount as often as ten times a day.

Some clinicians have attempted to evaluate dilaudid by determining its dosage and that of morphine which gave equivalent results, as shown in the accompanying table. In

Equivalent Doses of Dilaudid and Morphine

Author	Dilaudid, Mg	Morphine, Mg	Reason for Administration
Basch ¹⁶	2	10	Pain
Hemmerling ¹³	5	10-20	All purposes for which morphine would have been given
Krüskenper ²³	5	10-20	Pain
von Werthern ¹⁰	5	10-20	All purposes for which morphine would have been given
Birkholz ²⁰	2	10	Preliminary to anesthesia
Loewenthal ²³	2-2.5	10	Cough
von Oettingen, München med. Wchnschr. ⁷⁴	2	10	Preliminary to anesthesia
1184 (July 15) 1927			
von Hoesslin ²¹	2	20	All purposes for which morphine would have been given
Simenauer and Pulfer ⁸	4	10	Preliminary to anesthesia

addition, Bescht¹⁰ said that the effect of dilaudid on the central nervous system of man was the same as that of morphine but

that the effective dose was only from one third to one fourth as great, and according to Schwarz,¹¹ dilauidid fully replaced morphine in tuberculosis in one-tenth to one-fifth the dosage.

All of these comparisons were of the effect of the administration of single doses. In reference to the repeated use of dilauidid, the absence of tolerance has been reported frequently. In most cases, however, the author has said simply that in his experience he had not seen any evidence of tolerance or any necessity for increasing the dose and has not given details of the dosage, the duration of administration or other pertinent data of cases in which he believed tolerance had not occurred. There are a few partial exceptions to this general statement.

Fürst¹⁷ reported a case in which 5 or 10 mg was given daily for four months. Hemmerling¹⁸ gave a patient with sciatica 5 mg of dilauidid every other night and obtained analgesia of eleven hours' duration. At the end of four weeks the analgesia lasted from nine to ten hours. In another case, reported by the same author, after tolerance to morphine had been established, 75 mg of dilauidid gave ten hours sleep. At the end of six weeks the ten hours sleep was still obtained with the same dosage. However, that such an observation as the last mentioned establishes absence of tolerance is exceedingly doubtful. In a third case, one of cardiac decompensation, Hemmerling substituted 5 mg of dilauidid for 10 mg of morphine and said that that dosage continued effective during a period of four weeks. Von Werthern¹⁹ said that he had seen no occasion to increase the dose of dilauidid in repeated administration but was not willing to commit himself on the question of tolerance because his experience had been too brief. Von Hilger²⁰ reported that he had given for relief of pain eighteen 25 mg tablets weekly for a year without increasing the dose. Bescht¹⁰ stated that there was no tolerance established with small doses, from 2 to 25 mg, in several weeks (periods of twenty-four, thirty-one and thirty-seven days are mentioned) but that he had seen definite tolerance to larger, euphoric doses, 4 mg. Zahler²¹ reported that analgesic action did not diminish much during periods for which dilauidid was commonly employed and that there was no necessity for increasing the dosage. He cited a case in which the same dose continued to be used during six months for the relief of pain, though the quieting effect of the drug disappeared within three weeks. He said also that the respiratory center did not show habituation. In a later paper, Zahler²² described in general terms without details the changes in the blood sugar and blood calcium after single and repeated doses of morphine and dilauidid. The latter produced the same type of changes as the former, though the rates at which the changes were established were different. Crohn,¹² Klemperer¹³ and Paepfer¹⁵ each referred to the necessity of increasing dosage in persistently chronic and severely painful conditions.

In connection with these direct statements in regard to tolerance to dilauidid, there should be taken into account specific observations on the effective dosage of the drug in the presence of morphine tolerance. For example, Fürst¹⁷ reported an effective daily dose of from 5 to 10 mg after tolerance to from 10 to 20 mg of morphine had developed. Hemmerling¹⁸ said that 75 mg gave ten hours' sleep to a cardiac patient to whom after many weeks' use 20 mg of morphine gave only four or five hours' sleep. Kruskemper²³ described a patient, who, after receiving 70 mg of morphine four times a day, was relieved by 10 mg of dilauidid four times a day. Trautmann²⁴ reported that, after the development of morphine tolerance, 60 mg of morphine or 10 mg of dilauidid gave relief from pain for only two or three hours. Von Werthern,¹⁹ stating that 2 mg was the usual analgesic dose of dilauidid, gave 5 or 6 mg when 20 mg of morphine was required or when an individual was tolerant to 20 mg of morphine. Hartung,²⁵ who used 2 mg subcutaneously in painful conditions, found that 4 mg was required for patients who had been taking other narcotics

of this class. Loewenthal²⁶ gave from 6 to 8 mg to a patient who was tolerant to 80 mg of morphine and continued this dose for a month without further increase. Paulsen¹⁰ found that 2 mg of dilauidid three times a day controlled pain, cough and restlessness for many weeks after a tolerance had been established to 30 mg of morphine. Von Hoesslin²⁷ reported that, in the presence of tolerance, 4 mg of dilauidid and 40 mg of morphine, in one case, and 6 mg of dilauidid and 100 mg of morphine, in another case, gave the same results. Possibly of especial significance is the statement of Grage⁹ that he used dilauidid satisfactorily during the slow withdrawal of morphine. He did not record the dosage employed. It will be noted that some of these references are to authors who denied that dilauidid produced tolerance.

While the statements quoted tend to show that tolerance to small doses of dilauidid develops slowly, if at all, there is no doubt that cross tolerance has been demonstrated, the ratio of effective single doses was approximately the same whether or not tolerance to morphine had developed. It is seriously questioned whether in the long run dilauidid and morphine will be found to differ in their tolerance inducing properties.

Tolerance and addiction are intimately associated in the use of morphine, but the two are not necessarily concomitant, and observations that permit a conclusion in regard to the one do not of themselves imply the same conclusion in regard to the other. The authors reporting on the use of dilauidid have had relatively little to say about the danger of addiction. Most of them at the time of their report had had but a few months' to a year's experience in its use. A few commented on the presence or absence of euphoria, a symptom or condition which, if produced by the drug, would favor development of addiction.

Bescht¹⁰ There was no euphoria with from 2 to 25 mg, but it did occur after 4 mg. Grage⁹ The euphoria was different from that of morphine and in his opinion was dependent on the relief of pain. Zahler²¹ Usually there was no euphoria with doses sufficient to relieve pain, but a dose of 5 mg was strongly narcotic and euphoric. Bender,²⁸ Markowicz,²⁴ Simenauer and Pulfer.⁸ Dilauidid did not produce euphoria. Lullies.⁷ In fresh postoperative cases the narcotic and euphoric actions of other morphine preparations failed almost entirely after dilauidid. Rödel.²⁹ Slight euphoria followed the administration of 2 mg intravenously. Leyton.³⁰ Euphoria occurred in some cases. Alvarez.³¹ Euphoria was much less marked with dilauidid than with morphine. The last statement, however, seems to be based as much on impressions from the literature as on personal experience. Alvarez said in the same sentence with the remark in regard to euphoria that so far as he could learn no one had as yet become habituated to its use. This review of the literature shows that Alvarez evidently overlooked many instances of addiction that had been reported.

Trautmann²⁴ reported that he had seen no craving for the drug but added that his experience was not sufficiently extensive. Behlau³² in 1927 said "We must still think that in spite of the relative nontoxicity of dilauidid we have to do with a morphine preparation." Grage⁹ maintained that tolerance and addiction to dilauidid could occur. He cited two cases and remarked that the addiction was not as severe as after morphine and was more easily cured. Muller de la Fuente³³ reported a case of addiction of a year's duration. The dose had been increased from six or eight to fifteen or eighteen 2 mg ampules a day. Wolff,³⁴ in 1928, received 280 replies to questionnaires concerning addiction, in eight of which addiction to dilauidid was reported. In a later discussion of these replies Wolff³⁵ said that the report of addiction by eight observers was of special importance because at the time dilauidid was but little used. He added that the pharmacologic similarity of dilauidid to morphine made addiction to it readily understandable and that indeed it possessed a high degree of addiction property. In another place, Wolff³⁶ also mentioned

the satisfactory use of dilaudid in the treatment of morphine addiction. In his lecture on drug addiction before the Eighty-Third Annual Session of the American Medical Association, delivered at New Orleans, May 9, 1932, Wolff said "Dihydromorphinone has also proved valuable. It is often better tolerated and has the particular advantage that it depresses peristalsis less than morphine (hence its use after abdominal operations). Further, it has been shown both experimentally and clinically that it leads more slowly to habituation and addiction and its devotees are more easily cured."³⁷

Zahler,²¹ whose statements in regard to repeated doses have been quoted, claimed that in no case was there any difficulty in stopping the drug if dilaudid alone was taken. Paepfer¹⁶ reported that during a year and a half no abstinence symptoms had been observed. Von Hoesslin⁷ affirmed that, in regard to addiction, individuals vary with morphine and with dilaudid as well, and added, "Without doubt in many cases there is a marked tendency to addiction with dilaudid." Richtzenhain,³⁸ discussing the use of dilaudid and dicodid in nervous diseases, said that he had seen one case of addiction, although tolerance had never occurred, and in an appended footnote he said "I feel it my duty to add a word of caution. Dilaudidism and dicodidism are both already so often observed that we should be as cautious with the injection of dilaudid and dicodid as we have been with morphine injections." Leyton³⁰ in 1932 was unable to state from his own experience whether or not addiction would be produced.

Practically every clinical paper reporting the use of dilaudid makes some reference to its side actions in comparison with those of morphine. Many³⁹ have said that no side actions at all were observed, while others⁴⁰ admitted the infrequent occurrence of nausea, vomiting, dizziness and headache. Nearly all are agreed that nausea and vomiting are of much less common occurrence after dilaudid than after morphine. In a few cases it has been reported⁴¹ that a patient who had previously vomited after morphine did not vomit after dilaudid. Alvarez³¹ stated "Our impression is that nausea is produced more commonly with dilaudid than with morphine, but as yet we have not enough experience to be sure of this." At the time this statement was made the experience of the Mayo Clinic in this regard was of six months' duration.

All observers who mention the matter at all agree that dilaudid showed less tendency to produce constipation than did morphine. Kaiser⁴² reported that dilaudid as well as morphine increased the contraction of the vesical sphincter leading to cramp of the bladder, the resulting tenesmus requiring the use of the catheter.

A few papers⁴³ have commented specifically on the respiratory effects of dilaudid and especially on the danger of respiratory paralysis. Krehl,³ Hemmerling¹⁵ and Trautmann²⁴ reported that in exceptional cases 5 mg had slowed respiration to such an extent that respiratory stimulants were administered. Winternitz⁴³ said that dilaudid was somewhat more actively depressant than morphine to the respiratory center in man. Taterka and Pineas,⁴³ on the other hand, considered that there was less danger of respiratory paralysis in tabetic crises with dilaudid than with morphine, and Zahler²¹ thought that the effect on respiration with large doses would militate against the abuse of dilaudid.

REVIEW OF EXPERIMENTAL WORK

The experimental basis for the rather extensive clinical trial of dilaudid, which I have endeavored to review briefly, was very meager. In his report of the first experiments with the

substance, Gottlieb² said that in frogs from 0.5 to 1.0 mg caused cerebral narcosis followed by tetanic convulsions, that in dogs 4 mg produced narcosis and analgesia, and that in rabbits from 0.2 to 0.3 mg per kilogram reduced the respiratory minute volume to one half. He concluded that, as regards analgesia, respiration and narcosis in dogs, dilaudid was similar to morphine except that only one-half to one-fourth the dose by weight of dilaudid was needed. From experiments on rabbits, he concluded that the respiratory mechanism became tolerant to morphine but not to dilaudid. He gave daily injections of 1 mg of morphine per kilogram to each of two rabbits and 0.3 mg of dilaudid per kilogram to each of four others. About once a week the respiratory rate of the rabbits was studied. The animal was kept quiet in a small box for an hour or more. Then the respiratory rate was followed for about twenty minutes. The drug was injected subcutaneously and the respiratory rate followed for an hour. The animals receiving morphine were observed for twenty-nine days. On the first day the respiratory rate decreased from 39 to 30 and on the twenty-ninth day it increased from 43 to 53. Concerning the latter, the author said that the variation might lie within the limits of error of the method. If that was so, the initial decrease might also lie within the limits of error. Furthermore, I have shown⁴⁴ that the minimal effective dose of morphine to produce consistent decrease in respiratory rate in rabbits is 2 mg per kilogram, and van Dongen⁴⁵ demonstrated in 1915 his inability to obtain habituation to morphine of the respiratory mechanism of the rabbit. With dilaudid, Gottlieb obtained a 25 to 30 per cent decrease in respiratory rate at each observation throughout the experiment. These results support the contention that tolerance to dilaudid does not occur but they do not prove that tolerance to morphine did occur.

Joel and Ettinger⁴⁶ reported that in rats the intoxication picture of dilaudid was practically identical with that of morphine. Two milligrams of the former per hundred grams caused a two to four hour narcosis followed by an excitation stage. In animals in which a tolerance to morphine had been developed, 2 mg of dilaudid per hundred grams caused only the excitation. The authors concluded that a tolerance to dilaudid to the extent of a disappearance of the narcotic stage could be developed in rats.

Nau⁴⁷ performed a few comparative experiments on tadpoles, frogs, toads and fishes with dilaudid, morphine and heroin. All three paralyzed the central nervous system and were convulsant relatively in about the same degree as they were narcotic. All three paralyzed the frog's skeletal muscle and the toad's heart. In this respect dilaudid was twice and heroin was eight times as powerful as morphine.

Seeliger³⁰ injected morphine or dilaudid subcutaneously in rabbits with an abdominal window in order to observe their effect on peristalsis. Sufficient analgesia was produced by dilaudid to permit him to perform the operation for the insertion of the window without the use of another anesthetic. Peristalsis reappeared after morphine in from fourteen to sixteen hours, and after dilaudid in six hours. Unfortunately, the author did not state the doses used.

Schoen⁴⁸ injected dilaudid intravenously in rabbits in doses of from 0.5 to 50 mg per kilogram. One milligram per kilogram slowed the respiration, abolished the response to pain and abolished postural reflexes. General muscular tone was increased. Fifty milligrams per kilogram caused periods of extreme depression followed by periods of marked irritability. Two milligrams per kilogram subcutaneously had the effect of 1 mg intravenously.

Schmitt⁴⁹ gave dilaudid subcutaneously two or three times at intervals of seven days to each of twenty-two dogs. Five milligrams per kilogram caused emesis three times in fifty experiments. It slowed the heart, decreased the temperature and decreased sensitivity but did not induce sleep. With 10 mg per kilogram the effect was greater but its duration was not prolonged. The effect in young dogs was less prolonged than

that in older animals. An intravenous dose of 25 mg had the same effect as 5 mg subcutaneously.

Haffner⁵⁰ studied the analgesic action in mice of a large series of compounds. A clamp was placed on the tail and the extent of the pain reflex was noted. The minimal effective dose to produce complete analgesia was 0.0075 mg of morphine per gram of body weight, 0.0037 mg of heroin per gram, and 0.005 mg of dilaudid per gram.

Weiss⁵¹ described a new method for estimating analgesic action in rabbits by the prolongation, when morphine or an allied substance was injected intravenously, of the local anesthesia of the cornea produced by procaine hydrochloride. Measured in this way, the analgesic effect of from 2 to 4 mg of dilaudid was equivalent to that of from 8 to 20 mg of morphine.

In a more complete study than any made previously, Osman⁵² investigated the action of dilaudid on frogs, guinea-pigs, rabbits and dogs. He described a typical morphine picture for its action in frogs and in dogs and rabbits. The fatal dose for the frog lay between 200 and 400 mg per kilogram. In the dog, initial restlessness with vomiting and salivation was followed by depression, extreme muscular weakness, somnolence and analgesia, with marked slowing of the respiration. The depression was succeeded by a convulsant stage with exaggerated reflexes. The fatal dose for the guinea-pig was from 300 to 350 mg per kilogram and for the rabbit 200 mg per kilogram.

Osman studied in some detail the action of dilaudid on the respiration, the circulation and the central nervous system. He noted in rabbits a very marked slowing of the respiratory rate which was in part compensated for by an increase in depth, so that, with a decrease in rate to 15 per cent of the original, the minute volume was reduced to about one half. Dilaudid had little effect on the circulation, producing a slowing of the heart of central origin and only a slight fall in blood pressure. The analgesic dose for the rabbit was from 0.5 to 1 mg per kilogram, and as a sleep producer Osman considered dilaudid superior or always at least equal to morphine.

Finally, with himself as the subject, Rommelt⁵³ conducted a series of psychologic studies after the subcutaneous administration of dilaudid in a dosage of 3 mg. He reported that the drug produced definite depression of mental activity, and he discussed in considerable detail the factors involved. There was no euphoria, rather a growing distaste for the injections. Nausea and vomiting occurred, but no constipating action was observed. The effect of the drug was noticeable on the day following the injection.

PRELIMINARY REPORT OF PHARMACOLOGIC STUDY

Dihydromorphinone represents a comparatively simple type of change in the morphine molecule, one of the types of change included in the program of systematic chemical and pharmacologic study which has been instituted by the Drug Addiction Committee of the National Research Council. The study of this particular substance was begun in July, 1932. In this case the product was supplied through the courtesy of the Billhuber-Knoll Corporation to Dr. Small's laboratory, the chemical unit at the University of Virginia of the Drug Addiction Committee's organization, from which, after preliminary chemical study, it was sent to the pharmacologic unit at the University of Michigan. Our investigation of the substance is still incomplete, but it has progressed to a point at which a preliminary statement of our results can be made.⁵⁴

Our work has included the determination of the toxicity of dilaudid for mice and young rabbits, the intramuscular administration of the substance to cats for observation of analgesic and emetic actions, the subcutaneous administration to rabbits for a study of respiratory effects, and some experiments on intestinal action in dogs and rabbits. The methods employed have been fully described elsewhere.⁵⁵

As previously noted,⁵⁶ the toxic picture of dilaudid was very similar to that of morphine in both mice and rabbits, but the

fatal dose was much smaller and the convulsant action, as represented by the relation of the minimal convulsant dose to the average fatal dose, was greater. Dilaudid was more than six times as toxic as morphine for mice and more than three and a half times as toxic as morphine for rabbits, which is a higher degree of toxicity than that reported by Osman.⁵²

The minimal analgesic dose in cats of dihydromorphinone was only 0.17 mg per kilogram, or less than one-fourth the minimal analgesic dose of morphine (0.75 mg per kilogram) and about one-third the minimal analgesic dose of heroin (0.52 mg per kilogram). Cats have been seen to vomit with as little as 0.1 mg of dilaudid per kilogram and with 0.5 mg of morphine per kilogram, while none of the animals that received heroin have vomited. In dogs, vomiting has been seen after 0.05 mg of dilaudid per kilogram injected subcutaneously, although our dogs have rarely vomited after ten times that amount of morphine.

Dilaudid, like morphine, caused excitement in the cat, but an amount slightly greater than the minimal analgesic dose was required to bring this about. With morphine, analgesia and excitement were produced by the same dose. Possibly this difference indicates a higher degree of selective analgesic action in dilaudid.

In our experiments on rabbits, dilaudid has exerted a very powerful depressing influence on respiratory activity. One-tenth milligram per kilogram of the salt, dihydromorphinone hydrochloride, had as great an effect on respiration as 2 mg per kilogram of morphine hydrochloride, and a greater effect than 0.1 mg per kilogram of heroin. The respiratory rate and minute volume were decreased and the response of the mechanism to inhalation of carbon dioxide or of ammonia was less than normal. Oxygen consumption was little if at all affected by the 0.1 mg dose of dilaudid.

Dilaudid slowed the heart of the rabbit materially. In dogs also it had a very marked effect on the heart rate, producing definite slowing when as little as 0.05 mg per kilogram was injected subcutaneously. In both dogs and rabbits the drug had a pronounced general quieting effect.

In regard to intestinal activity, the minimal dose that would suppress intestinal evacuation in the rabbit was determined and a few experiments have been performed on dogs with Thury-Vella loops. In rabbits, the constipating dose of dilaudid was less than one-fourth that of morphine, while in dogs the same dose of each drug produced the typical modification of intestinal activity, particularly the increase in tone of the small intestine, characteristic of the action of morphine. Our experimental observations afford no explanation of the relatively weak constipating action of dilaudid reported clinically.

It should be understood that there are still many gaps in the experimental work on dilaudid, of which perhaps the most important are in relation to the questions of tolerance and addiction. We propose to undertake the investigation of these properties and to continue our study of the intestinal and emetic effects of the drug, as well as to endeavor to determine quantitatively its relation to morphine in sleep-promoting power. In the meantime, it would seem wise to delay the too rapid spread of the clinical use of the substance until the knowledge of its pharmacologic action is more complete.

CONCLUSIONS

It has been shown experimentally and clinically that dilaudid is powerfully analgesic and that, like morphine, it can depress the respiratory mechanism profoundly. At the same time, the experimentally established ratio between effective doses of morphine and dilaudid for the production of desirable effects is not materially different from the ratio between their toxic doses. *Clinical trial has not shown that dilaudid is free from tolerance and addiction evoking properties and while side actions such as nausea vomiting and constipation seem to occur less frequently after it than after morphine, the prolonged administration of dilaudid should be entered on with as much caution as would be exercised with morphine itself.*

The references that have been given are believed to be complete so far as experimental work on dilaudid is concerned, and it is considered that the selection of clinical papers fairly represents published clinical opinion. I was assisted by Dr. H. M. Krueger in the review of the literature and also in the experiments on dogs while the experiments on respiration were carried out by Dr. Charles I. Wright.

THE JOURNAL AND MEDICAL JOURNALISM

A STATEMENT BY THE BOARD OF TRUSTEES

Seldom in the past has space been utilized in THE JOURNAL to extol its own merit. Indeed, there has been little if any need for doing so. The increase in circulation, the material submitted for publication, the readiness with which subscribers have renewed their subscriptions, have been ample indication of their appreciation of what THE JOURNAL offers. During the last year, however, the world has been passing through what even optimists call a predicament. Great industries, to maintain sound financial status, have slashed their budgets, discharged employees, and in various other ways attempted to make both ends meet—financially. In the face of this situation the American Medical Association has carried on superlatively. THE JOURNAL has not lowered the standards that have brought it to its present high place in the field of medical journalism. It has not decreased the number of pages of reading matter in a volume. It has not raised its price to meet changing conditions and lowered income from advertising. Through efficient management it continues to develop sufficient income to carry on the multitudinous activities of the American Medical Association, although the margin now reached is barely in excess of those demands. In the face of this situation, nevertheless, a considerable number of physicians have begun the annual demand for a lowering of the price of subscription. In this connection it is interesting to report the results of several recent surveys of medical bibliography and of the place of THE JOURNAL in the medical bibliographic field.

The problem of the physician who subscribes to medical publications is to secure the maximum of usefulness with the funds available. There are published in the world today approximately eighteen hundred medical periodicals. Every one will grant that some of these are useless if not detrimental. Periodicals published by manufacturers of proprietary medicines, organs for propaganda issued by fly-by-night medical organiza-

tions, inferior publications issued merely to produce revenue from unacceptable accessories in the field of medical practice, hardly merit the name of medicine or of science in their titles. The *Quarterly Cumulative Index Medicus* indexes more than twelve hundred medical periodicals. In 1927, eminent librarians developed a method for determining the usefulness of a publication. They tabulated the references to it that appeared in a group of prominent publications issued throughout the world. R. L. Jenkins¹ undertook such a survey in the medical field and found that a study of the references in the *British Medical Journal*, the *Klinische Wochenschrift* and THE JOURNAL indicated that ten periodicals contained 35 per cent of the total references. THE JOURNAL led all other medical periodicals by far. Moreover, only 7 per cent of all bibliographic references antedated 1910, showing the value of purchasing current issues of leading periodicals rather than complete files of any publication, in building a useful medical library.

A similar study made by K. K. Sherwood² yields additional valuable information. Studying references that appeared in THE JOURNAL alone, he found that subscriptions to four magazines will supply the reader with one fourth of all noteworthy advances in medicine in the original articles. The leading fifty magazines contain 70 per cent of all noteworthy original articles. At present, he says, German is the most valuable foreign language for the use of an American physician. Finally, his studies showed the position of THE JOURNAL in the field of medical reference by revealing 411 references to THE JOURNAL, as contrasted with 82 references to the periodical next in line.

Because of the special problems created by the increasing cost of German medical publications, the Medical Library Association also has made a survey in this field. It was concerned especially with the cost of medical periodicals. Of particular value was the analysis of the per page costs of various publications. This analysis³ reveals the fact that the per page cost of THE JOURNAL to a subscriber is approximately one-sixth (0.16) cent, as compared with one-half (0.51) cent for the *British Medical Journal*, three-fifths (0.64) cent for the *Lancet*, one-third (0.34) cent for the *Presse medicale*, one-half (0.44) cent for the *Deutsche medizinische Wochenschrift*, and one-half (0.46) cent for the *Klinische Wochenschrift*, which are of the same type. In the field of specialistic publications the following comparative page costs are of interest. The *American Journal of Diseases of Children*, one-fourth (0.28) cent, the *Archives of Internal Medicine*, 0.24, the *Archives of Neurology and Psychiatry*, 0.30, the *Archives of Dermatology and Syphilology*, 0.35, the *Archives of Surgery*, 0.45, and the *Archives of Ophthal-*

¹ Jenkins, R. L. Periodicals for Medical Libraries, J. A. M. A. 97: 608 (Aug. 29) 1931.

² Sherwood, K. K. Relative Value of Medical Magazines, Northwest Med. 31: 273 (June) 1932.

³ Robert A. L. and Schaltenbrand, H. H. The Comparative Cost of Medical Journals, Bull. M. Lib. A. 20: 140 (April) 1932.

mology, 0 44, as contrasted with the *British Journal of Diseases of Children*, 1 88, *British Journal of Surgery*, 1 22, and *British Journal of Dermatology*, 1 71. Moreover, the German comparative figures are startling: *Deutsche Zeitschrift für Chirurgie*, 1 74, *Archiv für klinische Chirurgie*, 2 37, *Virchows Archiv*, 3 30, and *Zeitschrift für Kinderheilkunde*, 2 40. It is not surprising, therefore, that Dr. Fielding H. Garrison,⁴ after an analysis of these figures, should write that THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is, in respect of quantity and variety of material and illustrations, most reasonable of all in price, and, again, "Considering the profusion of photographic illustrations in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, it is obvious that other expensively illustrated periodicals cannot compete with the A. M. A. journal in extent of sales and subscriptions."

The problem of subscription to German medical periodicals has become an exceedingly difficult one for American medical libraries to solve. There seems to be no reasonable limitation on the number of volumes issued during a year or even on the price per volume. In recent years, libraries have had to pay \$92.25 for an annual subscription to the *Archiv für Dermatologie*, \$173.30 for the *Zeitschrift für die gesamte experimentelle Medizin*, and \$123.66 for the *Zeitschrift für Zellforschung*. Libraries that wish to keep up with German medical publications are being compelled to pay 70 per cent of their available money for German periodicals. They would not seem to be worth it. As a result of this analysis a special committee has addressed a letter⁵ to German scientific societies and editors asking them to make some attempt to decrease the size and number of volumes through briefer articles and careful editorial selection, and to arrange for fixed annual subscription prices, determining in advance the number of volumes appearing throughout the year.

The American Medical Association is to be congratulated on making available to the medical profession what is shown by analysis to be the leading medical journal of the world at the lowest price comparatively of any medical publication in the world. Membership and Fellowship in the American Medical Association give to the holder more for his money than is offered by any other scientific organization in the world and at a far lower price, even eliminating the vast services that are offered. Thus, members of the American Physicists Association pay \$10 and \$15 annually, the American Chemical Society, \$15, the American Bar Association, \$8 annually. Moreover, members of the British Medical Association pay \$15 annually. Consider in this connection such services directly to the individual practitioner as the package library service, the bibliographic

reference service, the answers to queries on every conceivable medical subject, and such general services as the *Quarterly Cumulative Index Medicus*, the work of the Bureau of Investigation, the Councils, Bureaus and Committees on Pharmacy and Chemistry, Physical Therapy, Foods, Medical Education and Hospitals, Health and Public Instruction, Legal Medicine and Legislation, most of them not duplicated by any other medical organization in the world, and one begins to attain some realization of what medical organization in this country represents and what it has accomplished.

Let us now be quite frank. This editorial has been written because of a certain minimal amount of agitation to lower the price of THE JOURNAL. To do so will mean certain reduction in both the amount and the quality of service that the Association is able to render to its members. Already there has been shrinkage of the working force to the bare essentials and a reduction of salaries for employees, none of whom have ever been paid salaries proportionate to those of similar positions for other organizations and certainly not for workers in commercial fields. The Association must maintain an adequate reserve to sustain its independence and to guard against disintegration and destruction. Since, as has been shown, members now pay far less than is paid for membership in any similar body in any country in the world, and since, as has been shown, they receive for their payment far more than is received by members of any similar body anywhere else in this country or abroad, reduction in the price of Fellowship or subscription should not be undertaken at the risk of hampering the work of the organization.

HOSPITAL INSURANCE PLANS

Already in various communities some hospitals have embarked on hospital insurance plans with a view to solving their own financial problems, and perhaps with a view to taking advantage of the interest created by recent discussion of the costs of medical care. The Committee on the Costs of Medical Care in its majority report recommended voluntary insurance or group payment as a means of solving problems in the medical field, whereas the minority was inclined to condemn such plans as leading directly to compulsory insurance and state medicine. In THE JOURNAL, last week, some of the factors of danger involved in such plans were indicated. The diversity of plans offered, the disruption already apparent among hospitals and physicians in some parts of the country, and the propaganda used to promote "pet" schemes by interested endowments, are indications of the seriousness of the situation and of

⁴ Garrison F. H. The High Cost of Current Medical Periodicals. Bull. M. Lib. A. 20, 165 (April) 1932. Reprint issued by the Medical Library Association, J. C. Harding, 11000 Euclid Avenue, Cleveland.

⁵ Letter sent to German scientific societies and editors asking their cooperation in bringing about a reduction in the cost of current German periodicals. Bull. M. Lib. A. 21, 90 (Jan.) 1933.

the need for more careful consideration than seems to be given to these problems by most hospital organizations and medical societies

It is refreshing in the midst of such doubts and disturbances as now assail the profession to find so cogent and pertinent a criticism of insurance as has just been offered by Dr Samuel C Harvey¹ in his presidential address to the New Haven County Medical Society. He says

There are certain essentials in providing any insurance. One is to limit the scope of the insurance to a field sufficiently narrow so that accurate figures may be obtained from which the actuaries may estimate the probable losses with a considerable degree of certainty. A second is the setting up of sufficient reserves to cover with complete safety any possible eventualities, and this requires capital. A third is that the insurer does not enter into the business of replacing losses in kind but only supplies the funds with which to replace such losses. An insurance company does not rebuild a house destroyed by fire, for this would mean entering into an entirely foreign field of activity which can be more efficiently and satisfactorily done by those already engaged within it. A fourth is that some mechanism be provided by which the insurance is sold with knowledge and skill so that it may be adapted to the needs of the individual concerned. A fifth is a sufficient spread of the field of the insured so that disaster to any one group will not destroy the reserves of the insurer. Taking all these things into consideration, it seems absurd to suppose that amateurs can offhand enter into the field of insurance and accomplish something that the professional organizations have not yet found themselves able to do. A customary statement is to the effect that removing the profit from insurance would enable this to be done with less cost, but unfortunately this also removes the expert in insurance matters, with the result that the gain by abolition of profit is more than balanced by the loss in efficiency. I believe, then, that if insurance is to be developed to cover the costs of medical care it must be done by those who are experienced in this activity, and that in practice means by reputable insurance organizations already in existence. Any other attempt will lead to subsidy by taxation, and where the state spends its funds it controls. There then grow up bureaus which contain within themselves the incentive to further growth, the only restraint being the exhaustion of the taxpayer. And the consumer always pays, but then by taxation through an intermediate body which necessarily abstracts from his dollar so that by the time it reaches the producer its purchasing value is sadly reduced.

With these reservations in mind, it would seem advisable to attempt to pick out some part of the costs of medical care which might be susceptible of insurance. Inasmuch as the largest factor in the serious illness is the cost of hospitalization, this would seem the logical point of attack. This has, of course, been long recognized and various attempts are being made by hospitals and groups of individuals, some of which are organized as corporations to provide insurance. None of these complies with the indications which have been stated above and therefore I believe they are essentially unsound and doomed to failure without they obtain subsidy from philanthropy or the state. That professional insurance organizations should study this problem in conjunction with hospitals and representatives of the medical profession seems obvious. The answer would seem to be in general along the lines of coverage, not complete but approximating actual hospital costs, for the use of plant and in addition limited coverage for professional fees, the disbursement to be made to the patient, the hospital and physician having, however, a primary lien upon such monies. With these limitations it should be possible to write an insurance the cost of which would fall under normal circumstances within the scope of the present average budget of the majority of families.

As was pointed out in our editorial last week, the presence of serious if not incurable ailments invariably gives rise to quack doctors, herb doctors, and recommendations by amateurs. The desires of financially innocent hospital executives, in this emergency, to participate in systems of insurance in which they and the institutions they represent bid fair to become the tools, if not the marks, of astute salesmen and commercial promoters would be ludicrous if they were not so sad. Every physician and hospital director should ponder well the five essentials emphasized by Dr Harvey in the statement here printed. They will do well to consider the results in communities which have already experienced the failures that he prophesies. Let us not too lightly sacrifice what modern medicine and the modern hospital have achieved in our attempt to gain the utopia which the Committee on the Costs of Medical Care so airily prophesies.

QUANTITATIVE CONVERSION OF CAROTENE TO VITAMIN A

In 1919 Steenbock¹ called attention to the similarity in the distribution of vitamin A and the yellow plant pigment carotene. Up to that time vitamin A had been recognized as a dietary essential for less than ten years, but many food substances had already been assayed for this factor and its natural distribution was fairly well defined. Yellow corn, yellow turnips, carrots and sweet potatoes were recognized as sources of the vitamin, whereas white corn, white turnips and white potatoes were not rich in this food factor. During the following ten years little attention was paid to this remarkable correlation between vitamin A potency and the pigment carotene, but within the past four years the intimate relationship between these substances has been demonstrated repeatedly by both chemical and biologic experimental methods. It is at present well established that the plant pigment carotene is transformed to vitamin A in the animal body. They are not identical substances: carotene is yellow, whereas vitamin A has little color, vitamin A exhibits an absorption of light of wavelength 328 millimicrons, carotene does not, both give a blue color with antimony trichloride but that with vitamin A shows an absorption band of 619 millimicrons, whereas that with carotene absorbs light of wavelength 590 millimicrons. Carotene is a crystallizable hydrocarbon with a cyclic structure, related to the terpenes, and the recent evidence indicates that vitamin A is probably a primary alcohol derivative of one half of the carotene molecule. On purely theoretical chemical grounds, therefore, it is reasonable that vitamin A should be derived from carotene. Indeed, the repeated demonstration of the vitamin A potency of carotene has led to the adoption of 0.001 milligram (1 gamma) of crystalline carotene as the international unit standard of vitamin A.

¹ Harvey, S. C. *Oikonomia Medika*, Yale J Biol & Med 5 323 (March) 1933.

¹ Steenbock, Harry. *Science* 50 352, 1919.

Although there is a considerable mass of evidence relating to the qualitative relationship of carotene to vitamin A, only recently have studies been reported bearing on the quantitative transformation in the animal body. Morgan and Madsen² determined by chemical methods the carotene content of fresh apricots and also the influence of freezing, drying and sulphuring on the amount of pigment remaining in the treated fruit. The loss of carotene in the dried fruit was about 40 per cent. The vitamin A potency of the apricots was then determined, as well as that of highly purified crystalline carotene, by the usual method of biologic assay depending on growth. When the gain in body weight of the experimental animals was related to the content of carotene in the fruit, it was found that the biologic value of fresh and of sulphured sun-dried apricots may be considered to be approximately 100 per cent of the expected value based on carotene determinations in these fruit samples.

The California studies, which are among the first to attempt to obtain a quantitative estimation of the transformation of carotene to vitamin A in the organism, indicate that within the possibilities of the present chemical and biologic methods of analysis the conversion of this plant pigment to vitamin A is nearly complete. Morgan and Madsen call attention, however, to the inevitable variations that might be expected in this relationship due to differences of absorption of the carotene, which depends, in turn, on the nature of the plant tissue of which it forms a part. It is on such quantitative measurements as these that the final chapters of the fascinating story of the biochemistry of vitamin A will be based.

Current Comment

PYRIDINE DERIVATIVES IN THE URINE

In view of the multiplicity of chemical compounds that make up the ordinary diet of man, it is striking that the accepted picture of those chemical transformations which constitute metabolism can be reduced to a relatively small number. This is especially pertinent to the changes occurring among the compounds of nitrogen in the body. A comparison of the known nitrogenous substances consumed with the number of compounds that account for the bulk of the nitrogen in the urine emphasizes the relatively few chemical pathways along which the great part of these changes are brought about. On the one hand is the diet with its large number of known compounds of nitrogen and certainly some unknown ones, on the other is the urine, almost all of the nitrogen of which can be accounted for by urea, uric acid, creatine-creatinine, hippuric acid, and ammonia. However, approximately 5 per cent of the urinary nitrogen is customarily reported as "undetermined," consisting of unusual compounds present in such small concentrations that the task of separation and quantitative determination is made extremely

difficult. A recent contribution to our knowledge of the make-up of this "undetermined" nitrogen of the urine has been made by Linneweh and Reinwein.¹ These investigators applied the Kutscher method of separation of bases with silver to 40 liters of urine and, after further manipulation, obtained 0.6 Gm of pure trigonelline chloride and 0.31 Gm of methyl pyridinium hydroxide. These substances are of interest because both are simple derivatives of the cyclic nitrogenous compound pyridine. The pyridine nucleus occurs in many alkaloids and trigonelline itself is widespread among the plants, notably in coffee. Furthermore, it has been shown that in the animal body trigonelline is derived from nicotinic acid, a derivative of nicotine. Less is known of the probable origin of methyl pyridinium hydroxide, though it has been said to arise from coffee during metabolism. Certain it is that the discovery of these unusual compounds in the urine will serve to call attention to the related compounds, in the food and their ubiquitous distribution. However, the question of greatest biochemical interest, namely, the manner in which the body handles these unusual and probably toxic substances, awaits the determination of the chemical nature of the combination of the pyridine derivatives as they occur in the urine.

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Twenty-Ninth Annual Meeting held in Chicago Feb 13 and 14 1933

DR. RAY LYMAN WILBUR, Washington, D. C.,
in the Chair

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

FEBRUARY 13—MORNING

Report of the Chairman of the Council on Medical Education and Hospitals

DR. RAY LYMAN WILBUR, Washington, D. C. During 1932, 642 hospitals were visited by members of the Council's staff. A wide range was covered, but emphasis was placed on (a) those hospitals that were approved or seeking approval for intern training, and (b) those hospitals approved or seeking approval for residencies in the specialties. Following out the action of the House of Delegates, the visitation of the hospitals for the mentally ill, 632 in number, has been practically complete. A beginning has been made in the inspection of hospitals for the treatment of tuberculosis, and also of the Negro hospitals, and at the request of the House of Delegates it is planned during the coming year to spend some time in studying the needs of small hospitals. Also, at the request of the House of Delegates, an analysis is being made of the staff membership of registered hospitals for the purpose of determining what percentage of the staff are members of the American Medical Association.

During the last fifteen years, the number of hospitals offering suitable training for interns has increased so that in 1932 the number of places available in approved institutions exceeded by 25 per cent the number of graduates from recognized schools. As hospitals are constantly striving to secure this approval, it is evident that this proportion will become greater. It is suggested that a solution of this difficulty may be found in extending the average duration of the internship.

The Essentials of a Registered Hospital have been revised so as to bring them up to date and the new statement has received the approval of the House of Delegates.

¹ Linneweh W. and Reinwein, H. *Ztschr. f. physiol. Chem.* 207: 48 (April 20) 1932

The report on hospital service was published in *THE JOURNAL*, June 11, 1932

Hospital Practice, a handbook of useful information for interns, has been completed and is ready for distribution

In some parts of the country, osteopaths and even chiropractors have claimed the right to practice in tax supported hospitals. Thus far the medical profession has been successful in persuading boards of management that the interest of the public is best served by excluding cultists from hospitals.

The Council has prepared and published during the year lists of physicians specializing in radiology and pathology. Formerly the Council approved laboratories in which radiologic or pathologic examinations were made. Experience, however, seemed to indicate that it was more important to analyze and appraise the qualifications of the individual who might be practicing radiology or pathology than to place the seal of approval on certain premises or organizations engaged in these fields. To this end, the *Essentials for Physicians Specializing in Radiology and Pathology*, respectively, have been revised and in their new form have received the approval of the House of Delegates.

The Council is also prepared to extend to other special fields of medicine the service which it has rendered in the fields of radiology and pathology, to the end that members of the medical profession and others who may be concerned may be able readily to distinguish those who have received training in the various branches of medicine from those who are merely self constituted "specialists."

During the past year, no additional medical schools have been approved. The University of Mississippi School of Medicine has been continued on probation.

The *Essentials of an Acceptable Medical School* have been revised in collaboration with a committee of the Association of American Medical Colleges.

A study has been made of the number of students repeating a part of the medical curriculum because of poor scholarship. Whereas seventeen schools had none repeating, a few schools had more than 10 per cent. It is of even greater concern that, in some instances, students who have failed utterly in the regular examinations have been promoted by executive order so as to avoid the necessity for reporting "repeaters." The executive order in medical education will have to be looked into.

Within the last five years there has been a larger number of technically qualified applicants than the medical schools of this country have been able to receive. Some of those who have been rejected, and many others who are not technically qualified, have migrated to European universities with the expectation of returning to this country to practice. At present there are probably 2,000 such American medical students abroad. In order to deal with this problem, the Council has brought together informally representatives of interested bodies for the purpose of discussing ways and means of protecting this country from men and women who may not be fully prepared. As a result of these conferences, it is hoped that uniform action may be taken by state boards throughout the country to exclude from their licensing examination all who have not fully met the prevailing standard of medical education in this country.

During the past year there has been published in revised form *A Standard Classified Nomenclature of Disease*, which, if it could come into general use, would greatly simplify hospital records and add enormously to their value.

I have tried to give some impression of the principal functions of the Council. It will be noted that certain real problems remain. For instance, the matter of the student educated in foreign institutions who expects to return to America, the hospital and what shall be done with it under existing conditions, whether such work as has been done for the radiologists shall be extended to the other fields of medicine.

Results of the Work of the Commission on Medical Education

SAMUEL P. CAPEN, PH.D., Buffalo. This will appear in full in *THE JOURNAL*.

DISCUSSION

DR. STANLEY RYERSON, Toronto, Ont. The report conveys the idea that medical training needs revision so that (1) recognition is given of the concept of medicine as a social

agency, (2) clinical methods will be brought into closer relationship with the fundamental sciences, (3) prevention, as a means of medical aid, will permeate the whole course, (4) the care and treatment of the patient, rather than of the disease, will be taught and, as Chancellor Capen has pointed out, medical education will constantly have to be recast and rearranged. A further point that the report suggests is the importance of the psychologic aspect of medicine. Twelve years ago, psychology was introduced as an elective course in the first medical year of the course at the University of Toronto. Students who might be interested in this mental aspect of practice followed this elementary course by other electives in practical psychology, abnormal psychology and psychiatry in the succeeding years. The number of students taking the introductory course as an elective had increased by 1931 to 70 per cent of the whole class, so last year psychology was incorporated into the first medical year as a compulsory course for all students. I think the time has come when psychology has to be recognized as one of the fundamental courses in the medical curriculum. "The course should be regarded as a unit and the instruction in individual departments ought to be presented with respect to the whole," reads the report. The fact that such a point of view does not exist at present is abundantly evident, with courses in anatomy taught as though the object were to train anatomists, in physiology to produce physiologists, in pathology to produce pathologists, in surgery to create surgeons. The statement of the curricular requirements and the methods used in instruction create the impression in the mind of the student that each subject is a unit in itself, a completion of the knowledge of which he is expected to accomplish in the time devoted to it. There is a textbook in each subject containing such a mass of information, the relative values of which he is unable to determine and the quantity of which is so great, that a picture of the subject as a coordinated whole, such as the structure of the body as a unit or the functions of it, is beyond his comprehension. If the idea of the unity of the course could be inculcated, the student will realize that, as the report says, "the educational sequence from premedical education to retirement from practice should be looked on broadly as a single problem, not a succession of isolated and unrelated experiences."

Whether that part of the Report on the Education of Medical Students adequately fulfils the first purpose of the commission of "making a study of the educational principles involved in medical education" is open to question in the minds of many. A study of whether the educational methods at present being used in medical colleges are based on sound educational principles does not appear to have been conducted or reported on as a specific investigation. That a solution to the problem of medical education is being sought in medical schools everywhere today is apparent. The one factor of this problem which is common to all medical colleges is that set down as the first purpose of the commission, namely, the educational principles involved. Should not a scientific study be made of the present principles of education that are in operation in the medical course? Are the methods used in instruction in accordance with accepted principles of education? Is the present method of teaching anatomy conducted in accordance with modern educational principles? Does the present method of laboratory work justify itself in the results obtained? Is the clinical teaching carried out in accordance with the principles laid down in the case study method of education? Is teaching done with an understanding of the learning processes of the student? Is the sequence of courses and the correlation of courses such as to make the course a unified whole? How can a shift in the interests and point of view of those in charge of medical education be brought about regarding the training of students and the new philosophy of medical responsibility? Books, journal articles and meetings have been drawing attention to the defects of medical education for ten or fifteen years and yet nothing has happened as yet to remedy effectively its weaknesses. The time has come when action by investigation of educational principles must be taken, if we hope to train adequately and effectively the medical man of the future to meet the professional, social and economic responsibilities that the report envisions.

An unprecedented opportunity exists for this association and the Association of American Medical Colleges to cooperate in instituting an investigation of educational principles and meth-

ods as they now exist in a representative number of medical colleges by one or more authorities in the field of professional education. I am aware that opposition exists to such a procedure for fear that it might jeopardize the freedom and independence of medical educators or interfere with the creation of the scientific and research point of view. Just as the fear of undergoing a physical examination by the patient is due to his ignorance of the value of the information that may be gained, so is the fear of an educational examination of the medical course based on a lack of appreciation and understanding of the present-day science of education. Education as a science has the same status in the American Association for the Advancement of Science as the medical sciences and is an established section of this body. Instead of the newer methods of education leading to a greater tendency to school-boy teaching, to greater rigidity, to more formality, to increased lockstep, to the return of the pedagogue of fiction, the whole basis of their philosophy depends on a steadily decreasing part taken by the teacher in his endeavor to educate the student to educate himself. The report endorses many of these newer principles in which a change in point of view is necessary. Why, where, when and how these new educational principles should be introduced into medical courses, can be discovered only by an educational survey by a trained educationalist.

In 1929, after a joint study committee of the Canadian Medical Association and the Canadian Nurses Association had given a good deal of thought and study to the problem of nursing education, it was agreed that nothing short of a thorough investigation by a competent experienced person should be secured and they procured Prof. George Weir, head of the department of education in the University of British Columbia, for this work. The "Survey of Nursing Education in Canada" was published in 1932. Why be afraid of such a procedure? If a similar survey is made of medical education, I am confident that the knowledge and information obtained, when considered along with this report, in which the professional aspects are dealt with so comprehensively, will enable universities and medical colleges to provide an eminently more satisfactory and effective medical education.

Some Phases of Medical Education in Europe

DR ALAN GREGG, New York. In June, 1924, I was sent by the Rockefeller Foundation to study medical research in Europe, spending about half the time in our Paris office and the other half in visiting and revisiting almost all the countries in Europe. I remained until January, 1931. The European universities had origins and initial circumstances quite different from those of universities in America. The first European universities began in many instances as spontaneous and rather informal segregations of scholars out of an established feudal society. The earliest universities in the United States began as colleges because the ministers of the Gospel and the teachers among the colonists were faced with the necessity of recruiting and training teachers and preachers for the colonists. Quite apart from historical considerations, there are other circumstances of a sociological category that affect medical education in Europe. Some of the implications of a dense population, as contrasted with a sparse settlement of the country, may be considered first. Norway, Sweden, Finland, parts of Russia, and even Scotland are countries where settlement is sparse in comparison with France, Germany, Belgium or Italy. The sparseness of settlement has a direct effect on medical school policy, since it is likely that the medical graduate will go to a community where there is within easy reach neither professional help nor professional competition. This sparseness of settlement means that the doctor must be reasonably well trained to meet a great variety of emergencies and sicknesses. It is, I think, quite natural that in these countries one finds implicit in the policy of the medical schools a definite sense of responsibility to turn out medical graduates that shall be competent and not dangerous, broadly trained and not narrowly specialized. Now, in countries of dense settlement one notes, on the other hand, the tacit and justifiable assumption that after graduation competition will do much that the medical faculty need not do, and perhaps cannot do, in giving long apprenticeship and intensive experience to the young doctor. It is hardly possible in Belgium for a young graduate to be the only physician in a wide area. He enters competition with others and he must wait

for the maximum responsibilities. It is common to see only 80 candidates successful in a competition of 800 for the most desirable posts. I think that in the United States we are suffering inevitably from the fact that we have both types of settlement, and that no single school can count on producing students exclusively for one or the other set of conditions. Closer examination of the sparsely settled countries of Europe leads to another consideration. Though sparsely settled, they contain the maximum population that can be sustained. The competitive life in Europe impressed me as more like a race in a narrow street. If one is at the very front, one can go very fast to find one's reward, but almost anywhere else the problem is not only to go fast but to keep from being run over by a competitor all too ready to take one's place. It may not be that we shall ever have in the United States the same ever-present competition that is characteristic of European universities, but, on the other hand, some day we may approach Europe in population density and the effect it brings.

In academic circles it is a competition not only for a livelihood but for place. European society gives to the professor-doctor especial recognition. Family pride is involved in this struggle for place, and pressure from all quarters concentrates on the student, not only in the university but in the secondary school perhaps as much or even more. The competition for place is a competition of endurance as well as speed, and longer training and broader training are the qualifications offered by the successful competitors. It is common to see a very close relationship between, say, a professor of clinical medicine abroad and his assistants, but not so close a relationship between the professor and the average run of students. From this relation with assistants have developed the so-called academic families, and the academic past of any young man is an important and widely known item in the evaluation of his real worth. In justice to professors who are almost victimized by this competition, I would suggest that it may in part explain the preoccupation in the eyes of casual visitors which seems to characterize some of the best men in the clinics and laboratories of Europe. I have seen this preoccupation misinterpreted again and again and I do not think that it is fair to attribute to it the interpretation that would be placed on it in the United States.

It is not sensible to attribute too much to the necessities of competition, but there is an almost inescapable conclusion that it results in a special sort of intellectual maturity in the young European which is not so commonly found in so-called younger countries. Naturally, attention in Europe is sharply concentrated, therefore, on the method of the selection of men for important positions. There is a degree of discrimination in the estimates of intellectual ability and character, there is an amount of rivalry, not always of an edifying sort, there is a tendency to widen the field of choice, there is a solicitude for creating methods of proving quality before the final choice, and there is even an amount of dickerings with the actual nominee for a professorship which is interesting and impressive. One sees young Germans obliged to leave the university of their choice, since they can get the coveted position only if they are called back to it. My attempt, therefore, is to pass on in this brief talk one or two facts which, I came laboriously to realize, are some of the considerations to bear in mind in interpreting the facts of medical education abroad.

DISCUSSION

DR E. P. LYON, Minneapolis. As I read over Dr. Gregg's paper, the following struck me as notable points. The first is the desirability that we study medical education in other countries, in Europe, and that we draw from there ideas for use in our own situation. The statement to the effect that some were beginning to think of medical education as self education ought to be the predominant thought in all our minds in the coming years. I think we have come to the time when standardization of curriculums and the dealing out of so much material which is to be taught is past. I think that means that we shall pay less attention to curriculum, to pedagogic details, to classwork, to the details of tenets, and so on, and that we shall bend every effort to tell the student that he has to get the stuff for himself and that what he will be will depend on how much he is able to make himself self educated, and it is not our business at all to educate him. In regard to the author's discussion of the difference in training to fit

people for places of less versus more dense population, I have not any definite opinion. Probably it is true that our students being educated in modern, highly equipped hospitals get less of the methods which would be used in out-of-the-way places to accomplish the same result, perhaps lose inventiveness, and perhaps are less able to tackle the situation in the country than students formerly trained. I feel that perhaps there should be among clinical teachers more of an effort to call attention to methods which can be used when the equipment is less extensive than that which we have in the teaching hospitals.

Regarding specialists' training, I have a feeling that we are past the period of the six weeks specialist, and that the young men nowadays who go into specialties make up their minds beforehand to a long period of training. There are certain important things that Dr Gregg left out. The first is that there is a tendency to a definite overcrowding of the medical profession, and I think the meeting of that emergency is the greatest problem now before medical educators. One cannot sit in a dean's chair and notice the struggle of young men to get located compared with twenty years ago and not be struck with the fact. I have thought, "How can it be settled under our American conditions?" and I must say my mind is very hazy, but I feel that the basic movement must come from the medical profession represented by the American Medical Association and from the medical educators as represented by this body and the Association of American Medical Colleges. I feel that the most drastic steps should be taken to meet it. And I favor such drastic steps on the sociological argument that it is bad for the people. Anything that tends to overproduction in the medical profession tends to the outcropping of all that is bad in medicine. At present the medical profession is a high-minded, honest and reliable profession, taken as a whole, but in its midst there are always some shysters, some quacks, some abortionists, some men who have not been impregnated with the ethics of the profession. When the exhibitions of competition become more drastic, I am certain that every one of those tendencies in the wrong direction will be exaggerated. As a protection for the whole people and not for the medical profession alone, I strongly advocate that we get right at this job to find out where we are standing.

DR DEAN LEWIS, Baltimore. I was glad to hear Dr Gregg say there are three things absolutely necessary in the education of the medical student. The first is observation, the second is reasoning, and the third is a knowledge of literature. In our present-day system of education they have very little of either. I have seen a great deal of interest in the statement that all education should be self education. In surgery, self education in fracture results in such things as crippling a patient in a case of fracture of the femur. That is self education, but it is hard on the patient. So far as the teaching of surgery is concerned, there are certain things a man has to know before he can take care of patients. In the first place, he has to know in the treatment of fractures the difference between a long fragment that he can control and a short one which he cannot control, and he does not learn that unless somebody tells him. There will be a lot of cripples if he goes on self education. Self education does not apply so far as surgery is concerned. There are certain things that one has to teach the student, and then he has to reason and observe. There are things that he has to be told repeatedly, and it is often repetition that gives the medical student the best part of his training. I also think there has to be a certain amount of discipline. There is a tendency among medical students to choose the things they like because they are easy.

DR AUSTIN A HAYDEN, Chicago. There is a question brought to mind by the diagram that is on exhibit outside the door, regarding the overcrowding of physicians in certain countries. I was surprised to learn that America has the greatest density of physicians per population and that the country that is second in physicians to population is Spain. Dr Gregg's observations, he says, have been gathered from the interviewing of professors, of government agents, and of medical educators in general. As a private practitioner of medicine, I should like to call attention to the fact that there is such a thing as a patient, and that there is such a thing as a private practitioner of medicine, on which these professors and government agents depend for the actual delivery of medical service to sick people.

DR ALAN GREGG, New York. I think that the point that Dr Hayden brings out is partially answered by the fact that so far as I know none of the professors with whom I spoke were full time professors. They were all doing some practice. A good many of them, if not the majority, had been doing practice quite apart from the universities previous to their university appointments. I did not use the word "self education" because it happens that I think that very rarely happens in pure culture. But what I think does happen is that the pressure and the seriousness of life that surround the European student make him realize that he is responsible and it is for him to choose people who will do teaching for him. A young man in Europe knows his professional circumstances are more serious than we have in this country. His education, in order to get into the school, is settled when he is about 13 or 14 years old, by being put into a course. So the load for the parents is one that begins at 13 and finishes around 27 or 28, but it really goes on further than that because one doesn't do very well in the first ten years. The parents have got to be ready to make at least supplementary support for their children during the years immediately following the obtaining of their degree and apparent entrance into practice. That reflects itself in a serious way in the whole atmosphere of society. The students feel it, and they don't get annoyed with some one who has to get something. Family reputation is involved, financial stability is involved, freedom of action is involved, and self respect is involved. They can't play with that. I am talking about the better grade of Europe. I know in Europe that there are a number of casual students, but I am not telling you what goes on in Europe in a judicious frame of mind, because then I should say we have certain things we can learn from Europe, and there are certain things in which we are doing better than they are doing in Europe. I would agree with Dr Lewis that there are large fields in medicine where teaching must take place, but what I want to point out is that in Europe it is probably a little bit less of the item of pressure from teacher and a little bit more of the item of succession from student, and that that is responsible for its being possible to leave to a certain extent some of the decisions regarding how much he shall take of this or that to the student. The very best men are the men most eager to get under the prolonged tutelage. It isn't a question of self education. They want to get under the prolonged tutelage of good men, and they will sell their souls to do it. The competition is strict. To answer the question Dr Hayden raised about Spain, the degree of Doctor of Medicine has in Spain a certain social value. When in Brazil I knew lots of professional politicians who went through school to get a degree of Doctor of Medicine. I feel that in Spain it is more than likely that the same factor is in play. There is also almost a perfect difference so far as what happens to the tail end of the profession. There are plenty of doctors in Spain not practicing because there are not enough persons to practice on, they are registered as doctors but are probably doing something else. They keep up their registration. I don't think that explains all of it, but it is enough to be a partial explanation.

Comments on the Internship

DR WILLARD C RAPPLEYE, New York. This article appeared in full in THE JOURNAL, March 25, page 873.

DISCUSSION

DR VERNON C DAVID, Chicago. Rising from the rank of medical student to that of a responsible house officer and therefore coming into much greater personal relationship with his attending man, one has a great opportunity to set an example in the moral issues involved in the practice of medicine. The influence of the late Frank Billings on his house officers is a case in point. Scientific honesty, kindness, equal interest in rich or poor, absence of sham or front, an appreciation of the changed psychology of the sick and a whole string of equally homely virtues developed a morale far removed from thoughts of fee splitting, commercial practice, too lofty dignity or careless work. There are not many Billingses, but every attending man can develop moral perspective in his house staff. It would seem important that men should have a rotating intern service. The surgical internship is not a proper place for training in operative technic but rather is an opportunity for further study of surgical principles. The intern should

make independent rounds and dressings as well as those made with his attending man, should do the laboratory work in his cases, should study the microscopic changes in specimens from his service, and should have and take time to read about his cases. Those things are on the shoulders of his attending man.

(To be continued)

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Tuesday and Thursday from 9 15 to 9 20 a m (central standard time) over Station WBBM (770 kilocycles, or 389 4 meters). The subjects for the week are as follows:

April 4 A New Deal in Food Advertising
April 6 Chocolate.

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 9 45 to 10 o'clock over Station WBBM.

The subject for the week is as follows:

April 8 Heart Pains and Palpitations

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

State Medical Meeting at Montgomery, April 18-21—The sixty-sixth annual meeting of the Medical Association of the State of Alabama will be held in Montgomery, April 18-21, under the presidency of Dr Samuel Kirkpatrick, Selma, and with the Montgomery County Medical Society as host. The governor of Alabama, Hon B M Miller, the mayor of Montgomery, Hon W A Gunter, and the president of the county medical society, Dr Charles E Robert Parker, Montgomery, will give addresses of welcome. Dr Kirkpatrick's speech will be on "Contributions of Medicine to Civilization." The scientific program will include the following physicians as speakers:

Harold E Simon Birmingham Clinical Syndromes of the Surgical Spleen.
Harry R Cogburn Mobile The Scope of Dermatology.
Emmett B Frazer Mobile Hematuria Its Great Significance.
John F Yarbrough Montgomery Acidemia Its Relation to Chronic Disease.
James R Garber, Birmingham, Prophylaxis in Labor.
John E Walker Opelika Hypothyroidism with Particular Reference to Its Cardiac Complications.
Charles E Robert Parker Montgomery Celiac Disease—Chronic Intestinal Indigestion.
Harry A M Simpson Florence, Incidence of Mental and Nervous Manifestations in Internal Medicine. Review of 100 Cases.
James Harold Watkins, Montgomery The Mechanism and Significance of Heart Pain.
James H Dodson Mobile Consideration of Some of the Anatomic Structures Dealt with in Treating Anorectal Diseases.
Alfred S Fraser, Dothan Acute Osteomyelitis.
George S Graham Birmingham Identification of Cancer Cells in Serous Fluids as a Diagnostic Measure.
Samuel L Ledbetter Jr Birmingham Congenital Pyloric Stenosis.
John D Sherrill Birmingham Ununited Fracture of the Neck with the Femur.
Walter F Scott Birmingham Prostatic Resection—Its Limitations and Complications.
James M Mason Birmingham Traumatic Arteriovenous Aneurysms.

A public meeting, Wednesday, will be addressed by Drs Dean Lewis, Baltimore, President-Elect, American Medical Association on "Medical Problems Confronting the Medical Profession," and Irvin Abell, Louisville, on "Recent Contributions of Science to the Field of Medicine." Dr John Shelton Horsley, Richmond, Va., will deliver the Jerome Cochran Lecture on "Cancer of the Stomach and Colon." Other guest speakers will include:

Dr Roy Wesley Scott professor of clinical medicine Western Reserve University School of Medicine Cleveland Clinical and Pathological Observations in 2 000 Cases of Cardiovascular Disease.
Dr Wiley R Buffington professor of ophthalmology Tulane University of Louisiana School of Medicine New Orleans Diagnostic Importance of the Eye.
Dr Hugh J Morgan professor of clinical medicine Vanderbilt University School of Medicine Nashville Thomsen's Disease A Clinical Study.
Dr Robert G Carothers Cincinnati Treatment of Fractures of the Ankle.

Dr Frank K Boland, professor of clinical surgery Emory University School of Medicine Atlanta Differential Diagnosis of Abdominal Tumors.
Dr Fred W Rankin, Lexington, Ky Curability of Cancer of the Right Colon.
Dr John J Shea, Memphis, Tenn, Management of Fractures of the Facial Bones.
Dr Raphael E Semmes, associate professor of surgery, University of Tennessee College of Medicine, Memphis Head and Brain Injuries.

A symposium on Bright's disease will be given by Drs James S McLester, Birmingham, Monroe A Maas, Selma, and Frederick W Wilkerson, Montgomery.

ARIZONA

Bill Enacted—H 46 has become a law, requiring all applicants for licenses to practice the healing art, as a condition precedent to examination by their respective "professional" boards, to pass examinations in anatomy, physiology, pathology, chemistry, bacteriology and hygiene, to be given by a board of examiners in the basic sciences.

ARKANSAS

Bill Enacted—S 361 has become a law, according physicians, dentists, nurses and hospitals treating persons injured through the fault of other persons liens on all rights of action, claims, judgments, settlements or compromises accruing to the injured persons by reason of their injuries.

CALIFORNIA

Health at Long Beach—Telegraphic reports to the U S Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended March 18, indicate that the highest mortality rate (24 6) appears for Long Beach, and the rate for the group of cities as a whole, 12 1. The recent earthquake in California, which caused its greatest devastation in Long Beach, is responsible for the resultant increase in the mortality rate. The mortality rate for Long Beach for the corresponding period last year was 11, and for the group of cities, 13 9. The annual rate for eighty-five cities was 12 4 for the eleven weeks of 1933, as against a rate of 12 5 for the corresponding period of last year.

Southern California Medical Association—The tentative program of the annual meeting of the Southern California Medical Association in Pasadena, April 7-8, is as follows:

Dr Emil Bogen Olive View Cause of Death in Consumptives.
Dr Norman J Kilbourne Los Angeles, Internal Hemorrhoids Comparable Results of Treatment by Operative and Injection Methods.
A Survey of 60 000 Cases.
Dr Markley C Cameron Jr Los Angeles Functional Dyspepsia.
Dr Earl M Tarr Los Angeles Relation of Vitamin B Deficiency to Metabolic Disturbances During Pregnancy and Lactation.
Dr George D Brown, Pomona Treatment of Acute Intestinal Obstruction.
Dr Samuel M Alter, Los Angeles The Acid Base Equilibrium.
Dr George S Sharp Pasadena Curability of Cancer by the Combined Methods of Irradiation and Surgery.
Dr Neville T Ussher Santa Barbara, Treatment of Bronchial Asthma with Physiotherapy.
Dr Carl R Howson Los Angeles Cavities in Pulmonary Tuberculosis Their Significance, Prognosis and Treatment.
Dr Howard L Updegraff, Los Angeles Reconstruction of the Burned Face.

A symposium on thermotherapy will be given by Drs Douglas R Drury, Los Angeles, John F Van Paang, Santa Barbara, and James Ross Moore, Los Angeles. The Friday evening session will be addressed by Drs Jacob C Geiger, health officer of San Francisco, on "Treatment of Carbon Monoxide Poisoning," and Arthur W Meyer, professor of anatomy, Stanford University School of Medicine, San Francisco, on "Attrition in the Human Body."

COLORADO

Venereal Disease Clinic—With the discontinuance of the clinic for the treatment of venereal diseases operated by the state board of health, because of a reduction in funds, the Denver health department opened its own clinic March 15. Five rooms have been made available on the third floor of the Police Building. It was stated, where indigent residents will be treated. Social service aid will be used to prevent the use of the clinic by persons who should obtain treatment from private physicians.

ILLINOIS

Warning About Rabid Dogs—The state department of health, Springfield, issued a warning, March 14, concerning dogs suffering from rabies. Three persons have died of the disease in the state recently, it was stated. Fifty of 100 dogs recently examined were found to be suffering from rabies.

Past Presidents Honored—The Kane County Medical Society, Dundee, presented badges of honor to all living past

presidents of the society at a meeting, February 15 Dr George J Schneider, Elgin, who served in 1903, is the oldest living past president Others are Drs Frederick C Schurmeier, Elgin, who held office in 1912, William H Bishop, Elgin, 1913, William H Schwingel, Aurora, 1915, Adam E Diller, Aurora, 1917, 1918 and 1919, Lawrence J Hughes, Elgin, 1920, George W Harin, Aurora, 1921, Ralph W Carpenter, Geneva, 1925, Carl P Struve, South Elgin, 1927, John W Drever, Aurora, 1928, and Hugh H West, Elgin, 1931 Dr Frank E Sumpson, Chicago, addressed the meeting on "Radium Treatment of Cancer"

Quack Collins Electrocuted—G Ward Collins of Springfield was reported to have been electrocuted while operating an x-ray machine in his office, March 10 According to the Department of Registration and Education of the State of Illinois, Collins has been an old violator in the chiropractic field When the clean-up was made in the department of registration and education and Mr J E Edwards, the present chief inspector, was put on the job that he has so well filled, Collins' activities were looked into, and in January, 1931, a warrant was issued The case was set for May, 1931, and was continued seven times Finally the state got the case to trial, and on Sept 29, 1932, G Ward Collins was found guilty on two counts A motion for a new trial was denied and a sentence of \$500 was imposed and he was given sixty days to file a bill of exception March 9, the state's attorney at Springfield was preparing an answer to Collins' brief, which was going to the appellate court

Chicago

Black, Rutherford, addressed the Bergen County Medical Society, Hackensack, March 14, on "Failing Heart of Middle Life" and "Coronary Disease," respectively —Dr Arthur L. Stone, health officer of Camden, was elected president of the New Jersey Health Officers' Association in February —Dr Leon T. Ashcraft, Philadelphia, was the speaker before the Gloucester County Medical Society, Woodbury, February 16, on "Urology as It Interests the General Practitioner"

NEW YORK

Physicians' Hobbies.—Rochester physicians held an exhibit of their leisure-time handiwork, including paintings, wood carvings, ship models, violins, photographs and various kinds of collections, at the Rochester Academy of Medicine, March 23. Drs Joseph B. Loder and Homer A. Harvey, Batavia, exhibited violins they had made, Dr George W. Corner has constructed a home-made telescope and Drs Cyril Sumner, Clarence P. Thomas and Joseph R. Mayer displayed ship models, the Rochester *Times-Union* reports. Artists included Drs John R. Williams, John F. Gipner, Henry B. Crawford, Istvan Gasper, George B. Carroll and Robert B. Kennedy. Among the collectors are Drs Williams, who showed pictures of Washington and Lincoln, Sumner, tropical and oriental fish, Alvah C. Remington, pistols, Mayer, old armor, Nathaniel W. Faxon old coins, Eldred W. Kennedy, stamps, William Douglas Ward, ancient clocks, George W. Goler old furniture, Grace A. B. Carter, medicinal plants, George W. O'Grady, autochrome plates. Workers in wood and metal include Drs Edward Parnall, Stearns S. Bullen and Morris F. Missal. Numerous photographers were represented in the exhibit including Drs Albert C. Snell, Graydon Long, James A. Quigley, Raymond W. Hawkins and Charles B. F. Gibbs

New York City

Sixth Harvey Lecture.—Michael Heidelberger, Ph D, associate professor of biological chemistry, Columbia University College of Physicians and Surgeons, delivered the sixth Harvey Lecture of the year at the New York Academy of Medicine, March 16

New Hospital at Medical Center.—The Institute of Ophthalmology of the Columbia University Medical Center, begun in 1931, was opened for patients in January. The new hospital, said to be the only one in New York devoted exclusively to treatment of diseases of the eye, is at Fort Washington Avenue and One Hundred and Sixty-Fifth Street. The building is nine stories high, with a capacity of eighty-six beds. The institute will have a staff of fifteen physicians, six interns and thirty nurses, under the direction of Dr John M. Wheeler, professor of ophthalmology, Columbia University College of Physicians and Surgeons, and head of the ophthalmologic service at Presbyterian Hospital. Margaret H. McCurdie, R.N., is superintendent of the hospital.

Admission to Dispensaries.—A committee representing hospital superintendents and the special committee on hospitals and dispensaries of the Medical Society of the County of New York recently established a schedule of eligibility for admission to dispensaries. It was agreed that a single person without dependents who earns \$900 or less per year should be admitted. For a family of two the annual income limit was fixed at \$1,400, and \$250 was added for each dependent in larger families. The total family income is to be considered in families in which parents and children are working. It was decided also that an acute illness for which the medical expenditure would not exceed \$25 should be considered a case for private care when the earnings exceeded the schedule adopted. The examining physician in the clinic would decide whether the illness is acute or chronic and whether it could be treated for \$25. The patient would then be referred to a social worker for decision on the ability to pay.

OHIO

State Medical Meeting Postponed.—The eighty-seventh annual session of the Ohio State Medical Association, which was to have been held in Akron in May, has been postponed till October.

Bill Enacted.—S. 9 has become a law, amending the state prohibition law so as to permit physicians to prescribe alcoholic liquors under the same general restrictions that are imposed by the Volstead Act and regulations promulgated thereunder.

Society News.—Dr Charles A. Doan, Columbus, addressed the Summit County Medical Society, Akron, March 7, on "Newer Immunological Concepts in the Control of Communicable Diseases." —Dr George T. Pack, New York, addressed the Columbus Academy of Medicine, February 20, on carcinoma of the stomach, and also students of Ohio State University College of Medicine, on "Physics and Biophysics of Radium." Dr Willard C. Stoner, Cleveland, spoke, February 27, on "Chronic Arthritis and the Rheumatic State."

OREGON

Bills Enacted.—S. 127 has become a law, prohibiting the dispensing of drugs to the public by means of automatic vending machines. H. 127 has become a law, requiring all applicants for licenses to practice medicine, osteopathy, chiropractic, naturopathy or any other system of the healing art, as a condition precedent to examination by their respective "professional" boards, to be examined in anatomy, physiology, pathology, chemistry and hygiene by a state board of higher education.

PENNSYLVANIA

Personal.—Dr Frederick H. Allen, Philadelphia, has been elected chairman of the eastern section of the Pennsylvania Mental Hygiene Committee for 1933. —Dr John Bruce McCreary, Harrisburg, was elected president of the American Association of School Physicians at the fifth annual session in Washington, D. C.

Bills Introduced.—S. 629 proposes to prohibit hospitals receiving financial aid from the state or from any political subdivision thereof from employing any alien who does not furnish proof from the federal government that he entered the United States lawfully. H. 1485, to amend the workmen's compensation act, proposes in effect, to make compensable any occupational disease contracted in the course of any employment covered by the act.

Society News—Dr. Hugh H. Young, Baltimore, will address the Pittsburgh Urological Association, April 10, on prostatic obstruction—A symposium on disease of the suprarenal glands was presented before the Lackawanna County Medical Society, Scranton, March 7, by Drs. Maximilian A. Goldzieher, Maurice Packard and Harry F. Wechsler, all of New York—Dr. Thomas G. Smonton, Pittsburgh, addressed the Cambria County Medical Society, Johnstown, March 9, on visceroptosis

Philadelphia

Newbold Lecture—Dr. Burton J. Lee, New York City, delivered the twenty-ninth Mary Scott Newbold Lecture of the Philadelphia College of Physicians, March 23, on "Cancer—A Community Health Problem"

Diphtheria Campaign—The Philadelphia County Medical Society has announced its annual diphtheria immunization campaign during April and May. For the convenience of physicians, toxin-antitoxin is to be supplied from distributing points in various parts of the city. The department of health will refer to private physicians all patients who come to the health centers and are able to pay. Special instruction in the technic will be given at the headquarters of the society, April 6-7 and April 13-14.

Scarlet Fever Epidemic in 1932—Philadelphia had the most extensive epidemic of scarlet fever ever recorded in its history during 1932, with 6,549 cases and 48 deaths. The only year since 1900 which approaches the record of last year was 1921, when 6,432 cases occurred, with 104 deaths. Statistics show that scarlet fever has been definitely on the increase since 1919, as there have not been fewer than 2,000 cases since that year. The nearest approach was in 1923, when there were 2,233 cases, with 34 deaths. Whooping cough was second in prevalence with 5,351 cases in which 57 patients died. Chickenpox was third, with 3,846 cases. The incidence of measles was reported to be unusually low—408 cases, with 1 death. The city had only 17 deaths from diphtheria, the lowest number recorded in its history. The health department received reports of 23,777 deaths, a rate of 12.01 per thousand of population.

RHODE ISLAND

Bills Introduced—H. 837 proposes in effect, that all applicants for licenses to practice medicine, osteopathy or chiropractic be first examined by the public health commission in anatomy, physiology, chemistry, bacteriology, pathology, public health and symptomatology and diagnosis before being examined by their respective examining boards. H. 860 proposes that all applicants for licenses to practice medicine, osteopathy, chiropractic, dentistry or podiatry pass examinations in anatomy, physiology, pathology, symptomatology and diagnosis, chemistry, bacteriology and public health, to be given by a board of examiners in the basic sciences before being permitted to present themselves for examination to their "professional" examining boards. No member of the board of examiners in the basic sciences is to be a member of the public health commission or of the various professional examining boards.

TENNESSEE

Bill Introduced—S. 342 proposes to authorize the governor to appoint a public health council, which shall formulate the policies of the department of public health and shall nominate the commissioner of public health for appointment by the governor.

Society News—Dr. Francis R. Fraser, London, England, addressed the Nashville Academy of Medicine, February 14, on "Generalized Osteitis Fibrosa and Hyperparathyroidism." Dr. Worcester A. Bryan addressed the academy, March 14, on cholecystectomy—Drs. Robert B. Wood, Knoxville, and Spencer B. McClary, Etowah, addressed the McMinn County Medical Society, Athens, February 9, on "Home Management of Diabetes" and "Management of Influenza," respectively—The Fentress County Medical Society entertained the Five-County Medical Society (Putnam, White, Overton, Cumberland and Jackson counties) in Jamestown, March 1, speakers were Drs. A. H. Crouch, Forbus, on pelvic inflammation, John T. Moore, Algood, importance of medical organizations, and William C. Officer, Monterey, pneumothorax—Drs. William H. Reed, Kingsport, and Aaron Cole, Piney Flats, addressed the Sullivan-Johnson Counties Medical Society, in Kingsport, March 1, on appendicitis—Dr. Henry C. Long, Knoxville, addressed the Knox County Medical Society, February 28, on "Functional Digestive Disturbances"—Dr. Thomas L. Bowman, Harriman, addressed the Roane County Medical Society, February 21, on acute prostatitis.

TEXAS

University News—Dr. Henry Reid Robinson, associate professor of obstetrics and gynecology, has been named professor of clinical obstetrics and gynecology at the Medical Department, University of Texas, Galveston. Members of the Texas senate were guests of the school, February 11, when Dr. Edward H. Cary, Dallas, President, American Medical Association, addressed the legislators on the cost of medical care.

Bills Introduced—H. 829 proposes that physicians, in the absence of express contracts to the contrary, may not recover in court actions for their fees more than indicated below: office consultation, \$1, house call, \$2, and traveling expenses not to exceed 25 cents per mile, major operation, \$100, minor operation, \$10, visit while in hospital, 50 cents. S. 459, to amend the medical practice act, proposes that the act shall not be construed to apply to a member of any church who treats human ailments by prayer or spiritual means, as an exercise or enjoyment of religious freedom, if he does not prescribe or administer drugs or medicines, or assume the title of "Dr.," or hold himself out to be a physician. Such a person, however, is not to be exempt from the quarantine and sanitary laws of the state.

VIRGINIA

Hospital News—The seventh annual spring graduate course offered by the Gull Memorial Eye, Ear and Throat Hospital, Roanoke, has been postponed for this year because of economic conditions—The third annual graduate clinic for Negro physicians will be held at St. Philip Hospital, Richmond, June 19-July 1. Physicians from other states will be admitted this year.

McGuire Lectures—The program of the Stuart McGuire Lectures for 1933, to be given April 25-27 at the Medical College of Virginia, Richmond, will be devoted to the cardiovascular system. Dr. Ronald T. Grant, University College Hospital Medical School, London, will give three lectures on "Pathology of Endocarditis" and one on "Arteriovenous Anastomoses in Human Skin," and Dr. Tinsley R. Harrison, Nashville, Tenn., will lecture on cardiac dyspnea. Dr. Louis Hamman, Baltimore, will hold a clinicopathologic conference and Dr. Paul D. White, Boston, a cardiac clinic.

WISCONSIN

Bills Introduced—S. 282 proposes to make it unlawful for any person to experiment or operate in any manner on any living dog, for any purpose other than the healing or curing of that dog. A. 672 proposes to prohibit the possession, use and sale or other distribution of any contraceptive drug or device or the dissemination of birth control information. The bill, however, is not to apply to licensed physicians who, in their opinion, find it necessary to prescribe methods to prevent communication of disease.

GENERAL

Alcohol Salesman Is Impostor—A man using the name Robert H. Downs is reported to be taking orders from physicians and dentists for alcohol under the fraudulent representation that he is a salesman for the U. S. Industrial Alcohol Corporation, Frankford Distilleries and Italian Swiss Colony Wineries. He carries business cards and order forms on which the names of these firms are misspelled and which bear a prohibition permit number that does not exist. He takes an order from a doctor or dentist, collects cash and disappears. According to the report, Downs started his solicitation in Nebraska and has appeared in Iowa, Minnesota and South Dakota. He was last heard of in Idaho. It is believed that he is working toward Seattle.

Pharmacists Opposed to Handling Beverage Liquors—The council of the American Pharmaceutical Association, in view of suggestions that malt liquors be distributed through drug stores, adopted a resolution protesting against any legislation permitting or requiring such distribution. The resolution points out that pharmacists are now charged with the distribution of alcoholic liquors for medicinal purposes and that public welfare and public health require that it be kept entirely separate from the distribution of such liquors as beverages. It further declares that the distribution of alcoholic malt beverages in drug stores would be inappropriate "because it would be contrary to the essential purpose and important responsibilities of pharmacy in relation to the people and to public health and because, through such distribution,

an activity foreign to its purposes and ethics would be introduced"

Society News—Dr Peter Whitman Rowland, Oxford, Miss, was named president-elect of the Mid-South Post-Graduate Medical Assembly at the annual meeting in Memphis, Tenn., February 16. Dr Alexander B. Dancy, Jackson, Tenn., was installed as president and Drs Henry King Wade, Hot Springs, Ark., Augustus Street, Vicksburg, Miss., and Frank J. Runyan, Clarksville, Tenn., were elected vice presidents. Dr Arthur F. Cooper, Memphis, was reelected secretary. Officers were elected at the annual meeting of the Pacific Coast Surgical Association in Del Monte, Calif., February 23-25, as follows: Drs Ernst A. Sommer, Portland, Ore., president, Thomas M. Joyce, Portland, and Sumner Everingham, Oakland, Calif., vice presidents, and Edgar L. Gilcreest, San Francisco, secretary. The 1934 meeting will be held in Portland the last week-end in February. Dr William T. Pride, Memphis, was elected president of the Southern Interurban Gynecological and Obstetrical Society at its third annual meeting in Memphis, February 13. Among speakers on the program were Drs Henry Schmitz, Chicago, on "Economic and Technical Problems in Radiation Therapy", Joseph L. Baer, Chicago, "The Third Stage of Labor," and Jennings C. Litzenberg, Minneapolis. Dr Percy H. Wood, Memphis, is secretary.

Medical Bills in Congress—*Changes in Status* S 562 and H. R. 1718, relating to the prescribing of medicinal liquor, have been ordered favorably reported by the Senate and House Committees on the Judiciary, respectively. *Bills Introduced* S 193, introduced by Senator Capper, Kansas, proposes to amend the laws of the District of Columbia relating to degree-conferring institutions, so as to permit institutions heretofore incorporated under such laws, and operating exclusively in a foreign country, to use the words "Federal," "American" etc., in their titles. S 759, introduced by Senator Shipstead, Minnesota, proposes to authorize the Reconstruction Finance Corporation to make loans, in the aggregate amount of not to exceed \$25,000,000, to any public or private hospital organized under the laws of any state. S 783, introduced by Senator Copeland, New York, proposes to prohibit the counterfeiting of any medicine or preparation recognized in the United States Pharmacopeia or National Formulary for internal or external use, and any substance or mixture of substances intended to be used for the cure, mitigation or prevention of diseases of either man or animals. H. R. 3829, introduced by Representative Henney, Wisconsin, and H. R. 3902, introduced by Representative Mitchell, Tennessee, propose to regulate the importation of milk and cream, and milk and cream products, into the United States. H. R. 4135, introduced by Representative McSwain, South Carolina, proposes to authorize the acquisition of additional land for the use of the Walter Reed General Hospital.

Bequests and Donations—The following bequests and donations have recently been announced:

New York Post Graduate Medical School and Hospital \$5,600 as a gift from Mrs. Henry S. Rea to establish the Oliver Rea Scholarship Fund and for research in bacteriology in the department of pathology. St. Luke's and Children's Homeopathic Hospitals Philadelphia \$10,000. Grenfell Association of America for St. Anthony's Hospital American Mission to Lepers New York and Pennsylvania Institution for the Instruction of the Blind Philadelphia \$5,000 each by the will of the late Florence Ludwig. King's Daughters Hospital, Madison Ind. \$10,000 in the will of Mrs. Elizabeth Heberhart. Winona General Hospital Winona, Minn. will receive the bulk of the estate of the late John Dietze valued at about \$200,000. Children's Mercy Hospital Kansas City Mo. about \$25,000 by the will of Mrs. Emma W. Robinson. Presbyterian Hospital Chicago \$25,000 from the estate of the late John Brackett Lord.

New England Hospital for Women and Children, Boston, \$15,000 by the late Hannah H. Kimball. Vassar Brothers Hospital, Poughkeepsie, N. Y., \$25,000 by the late Johnston L. Redmond. Philadelphia Freemasons Memorial Hospital, Elizabethtown, \$10,000 by the late Charles K. Channon.

PHILIPPINE ISLANDS

Medical Election—At the annual meeting of the Philippine Islands Medical Association in December, 1932, the following officers were elected: Drs Antonio C. Villarama, Manila, president, Sixto A. Francisco, Los Banos, Laguna, and Marcelino Asuzano, Pasig, Rizal, vice presidents, and Antonio S. Fernando, Manila, secretary-treasurer.

FOREIGN

Medals Awarded—Prof. Edward Mellanby of the University of Sheffield, England, has been awarded a medal of the Royal Society of London for his work on dietary factors, especially in rickets. Dr C. E. Correns, director of the Kaiser Wilhelm Institute for Biology, Berlin-Dahlem, will receive the Darwin medal for research on genetics, and Dr Torwald Madsen, director of the State Serum Institute, Copenhagen, will receive the Buchanan medal for work on immunity, especially in relation to diphtheria antitoxin.

Honorary Degrees—The Faculty of Medicine of Lyons, France, at a ceremonial, Nov. 3, 1932, conferred the degree of doctor honoris causa on Prof. Emil von Grodz, professor of clinical ophthalmology and formerly dean in the Royal Hungarian University of Budapest Faculty of Medicine, Baron Sandor Koranyi, professor of medicine in the same university, Prof. Edvard Ehlers, physician-in-chief to the community hospital of Copenhagen, Denmark, and Professor Jean Verhoogen of the University of Brussels, president of the permanent committee of the International Association of Surgery.

Cerebrospinal Fever in Cairo—An epidemic of cerebrospinal fever in Cairo, Egypt, during 1932, is described in the *Journal of the Egyptian Medical Association*. In the epidemic, which reached its peak, March 4, there was an aggregate of 980 cases, in which 422 patients died, making a case mortality rate of 42.3 per cent. During the preceding year 413 cases were reported with 246 deaths, giving a case mortality rate of 59.6 per cent. Cairo has not been totally free from the disease since 1909, although there had been a downward trend from 1916 until 1929. The epidemic of 1931-1932 reached its peak five weeks earlier than that of 1930-1931.

A New Medical Journal—A new review for the medical profession of the Mediterranean countries and the "Middle East," entitled *Folia Medica Orientalia* has recently been established in Jerusalem. The publication is to appear in sections, each devoted to a specialty. The *Folia Ophthalmologica Orientalia* and *Folia Oto-Laryngologica Orientalia* have already appeared and the *Folia Medicinæ Internæ Orientalia* is to be printed shortly. Departments of surgery, dermatology and pediatrics are to be added within the year. At present it is published in English, French and German and it is expected that articles in Italian and Spanish will be accepted later. Dr Aryeh Feigenbaum, Jerusalem, is responsible editor of the group and editor of the ophthalmologic journal.

Government Services

Dr Sayers Returns to Public Health Service

Dr Royd R. Sayers of the U. S. Public Health Service, who has been assigned to the U. S. Bureau of Mines for the past sixteen years, has been transferred back to the service to take charge of the division of industrial hygiene and sanitation. Dr Albert Eugene Russell will succeed Dr Sayers.

Dr Rossiter Appointed Surgeon General of Navy

Dr Perceval Sherer Rossiter has been appointed surgeon general and chief of the Bureau of Medicine and Surgery of the U. S. Navy, with the rank of rear admiral, for a term of four years. The Senate confirmed the appointment, March 16. At the time of his selection, Surgeon General Rossiter was commandant of the Naval Hospital in Washington. He is a graduate of the University of Maryland School of Medicine, Baltimore, class of 1895. Surgeon General Rossiter, who is 58 years of age, was appointed an assistant surgeon in the navy in 1903, and, in 1924, was commissioned a captain of the medical corps.

Another Phase of "Social Reform"

Attention has recently been called in *THE JOURNAL* (March 4, p 673) to the extraordinarily wide meaning given by the courts to the term "accident" in the workmen's compensation act. A man died from angina pectoris while cleaning out metal dross from a pot, and in spite of argument to the contrary the judge held that he had suffered a personal injury by "accident" which accelerated his death, thus entitling his family to compensation. An appeal was made to higher courts, which upheld this judgment. Though the personal injury could not have happened but for disease of the coronary arteries, the combination of disease and employment made it "a personal injury by accident." The *Lancet* has reviewed some previous similar legal decisions. In 1910 the leading advocate of the day, Sir John Simon, now foreign secretary, tried in vain to persuade the judges that injury by disease cannot be injury by accident. He was dealing with the case of a workman who suffered from an aneurysm in such an advanced stage that it might have burst during sleep. He was only tightening a nut with a spanner, an operation requiring no special strain, but the aneurysm burst and he died. The house of lords (the highest court) decided that this was an accident arising out of his employment. Lord Macnaghten in giving judgment explained the reasons as follows. An aneurysm is an unnatural or abnormal dilatation of an artery, still it is part of the artery and so part of the man's body. The man "broke part of his body." The fact that his condition predisposed him to such an accident seems to me to be immaterial, the work was ordinary work but it was too heavy for him. The fact that the result would have been contemplated as certain by a medical man if he had diagnosed the case is nothing to the purpose." In another case a workman ruptured himself in turning a wheel and the house of lords unanimously held that it was personal injury by accident. In a further case the judges stated that employers must pay compensation for internal injuries occurring in the course of workmen's employment no matter what his state of health. The *Lancet* concludes that "the case where a man carries about with him a fatal disease becomes a serious industrial problem." Would more frequent and systematic examination help to solve it? It could do so only by refusal to employ any one suffering from or even suspected to be suffering from any serious disease. Thus many men quite capable of suitable work would be prevented from earning a living. This would be a burden on the state and ultimately on industry. But one of the evils of democracy is that this consideration is disregarded, though such disregard in the pursuit of so-called social reform is largely responsible for our present industrial plight.

The Transmission of Yellow Fever over Continents

The possibility that increased facilities for traveling by train and air might lead to yellow fever being carried from West to East Africa and ultimately across Asia was put forward as a great danger at a meeting of the advisory committee of the Ross Institute for Tropical Diseases. Mr John Still of the Ceylon Association in London said that the death rate in the outbreak of yellow fever in Rio de Janeiro in 1929 was 59 per cent. Airplanes had rendered it possible to cross Africa within the period of incubation. The question also arose whether infected mosquitoes might not be carried by airplanes. The mosquito remained infected as long as three months

Experiments had shown that mosquitoes released in ordinary postal airplanes traveled 1,250 miles and survived three stops in airdromes where the crews were changed and baggage and passengers transferred. Twenty-two per cent of the test mosquitoes came through alive. It was known that thirteen species carried yellow fever and that monkeys, mice and other animals could be infected. Since the principal yellow fever mosquito was abundant all over the tropics, including East Africa and tropical Asia, the possibility of the disease being transferred by airplanes suddenly became of importance to the world. The permanent committee of the Office international d'hygiène publique, whose delegates represent fifty governments, has been engaged since 1929, in cooperation with the International Commission for Air Navigation in reviewing the risk of transmission of infectious diseases by aircraft. The result is the International Sanitary Convention of 1932, which regulates quarantine measures. None of its provisions have received more careful study from every angle than those relating to yellow fever. They are based on the recommendations of an expert commission of representatives of the British, French and Belgian possessions in Africa, of British India and of the American countries interested in the problem. At present no lines of air traffic have been established between the West Africa regions where yellow fever is endemic and other parts of Africa where the disease is unknown. The members of the International Sanitary Convention for Aerial Navigation unanimously agreed that in countries where yellow fever may exist they should not await the appearance of recognizable cases but take steps to search for unrecognizable ones by biologic methods and that measures for preventing spread by aerial traffic should be taken at the port of those areas where the disease exists.

The Cost of Medical Education

The number of students enrolled in the French facultes de medecine continues to increase, far beyond the needs of the population, leaving out of the count the foreign students who are supposed to return to their native countries, although it appears that many of them remain in France. The number of new physicians entering medical practice, each year, greatly exceeds the number of deaths and retirements. The income of the physicians, except for the eminent practitioners located in the large centers, is modest indeed. In vain have the medical syndicates endeavored to induce the directors of the lycees and the colleges to use their influence with the parents of pupils who are graduated from these schools to direct their attention away from the profession of medicine, by emphasizing the disappointment that is in store for most of the younger physicians. With this in view, a journal published recently the cost of a medical education up to the time when a physician may count on acquiring a paying practice. The items include the cost of schooling, beginning with the first class in the lycee, and comprise the first five years of practice, years in which the profits from the profession do not cover the cost of living. The total is placed at 116,385 francs (about \$4,650). In this figure, the cost of enrolment and of the examinations amounts to nearly 4,000 francs (\$160). To this sum must be added the cost of a student's living for five or six years. These figures represent only the minimum of expenses absolutely required. If the future physician aspires to a position a little out of the ordinary, he must prepare for the competitive examination leading up to the post of hospital intern and chef de clinique, and then hospital physician. In that case, the duration of the studies is tripled, and the cost of living, without immediate financial profit, is greatly extended. The poor student, who cannot count on his family sending him an ade-

quate monthly check, is compelled to perform humble tasks outside his study hours, in order to eke out his slender income. Some students drive taxicabs at night or serve as ushers in theaters and motion picture houses.

Tuberculosis in Algeria

A great effort is to be made to reduce the spread of tuberculosis among the natives of Algeria. Prof. Leon Bernard, vice president of the Comité national de défense contre la tuberculose, has been sent to Algeria by the ministry of public health, charged with the organization of a new program of action in collaboration with the governor general. The consulting commission on tuberculosis, created last summer at Algiers, has already studied various prophylactic measures and the organization of hospitals. The campaign against tuberculosis presents great difficulties in Algeria, owing to the low standards of hygiene among the natives. The campaign that is to be undertaken, for which the appropriations are generous, is designed to check the progress of tuberculosis. A large number of the natives of Algeria were called to France, after the war, to supplement the lack of man power caused by the loss of a million and a half men, most of whom were farmers and workmen. These Algerian immigrants, mostly, were or became addicted to alcoholism, living in squalor and easily contracting tuberculosis in the factories. On returning to their country, where they were not so welcome owing to the unemployment among workmen, they brought tuberculosis into their native regions. Now, however, the public health service of Algeria has become active. The following figures give an idea of the extent of this movement. In 1920 the expenditures in this field amounted to about \$800,000, today they have risen to nearly \$5,000,000. The number of hospital beds has increased, in ten years, from 3,600 up to 6,900 beds for patients, and from 750 up to 2,150 beds for aged persons. The number of hospitalizations in 1910 was 35,000, in 1920, 42,000, and at present the number exceeds 70,000. The disappearance of epidemics, the diminution of the mortality, and the increase of the population (50,000 a year) prove that this effort is beginning to show results.

Roentgen Sound Film

The Hochschule für Musik has a radio experimental station in which Heinz Grosse has produced a film in which he synchronized roentgen pictures with corresponding sound records. One sees, for example, the diaphragm and heart of an athlete working in rhythmic agreement. The eye and the ear follow the motions and sounds associated with articulated words. Even when a person is silent, the sounds of his heart will be caught by the transmitter and will furnish an accompaniment to the roentgen pictures showing the pumping activity of the heart. Since heretofore heart sounds and murmurs have been reproduced without distortion by the method of Dr. Jacobsohn, he has been endeavoring to make records suitable for instruction purposes, and secondly, to reproduce the heart sounds and heart murmurs synchronously with the heart movements. From a number of single roentgen negatives, systole and diastole are selected and positives are prepared from them, the transitional movements between the two phases are represented artificially. Thus one procures a roentgen film of heart action, by taking into account the time factors affecting heart action and the speed with which the film pictures are presented, one can figure out the number of "frames" required for the various phases. For the preparation of the individual frames, Jacobsohn constructed a camera that represents a combination of photographic apparatus and cinema camera. The sound films that were first prepared and presented (a normal heart and

a heart with aortic insufficiency, which in the roentgenogram shows a projecting left ventricle and aortic arch) were synchronized with the artificial heart sounds. These artificial sounds, which Jacobsohn presented a year ago before the Berliner Medizinische Gesellschaft, are especially suitable for a sound film because of their freedom from disturbing factors in connection with high amplification (THE JOURNAL, April 2, 1932, p. 1199).

For the purpose of synchronization, Jacobsohn uses an electrical cardiac tachometer, which has a device gaged according to the frequency of the heart beat and connected with the heart sound generator. In this manner the number of sounds or murmurs produced when the film is reeled off at a given speed is determined and thus a synchronism between the pictures and the sounds is produced. The didactic value of the new method is based on the simultaneous optical and acoustic record of the heart action under normal and pathologic conditions.

Voluntary Sterilization

As times change, opinions change, and that applies also to medicine. In a recent letter (THE JOURNAL, Aug. 27, 1932, p. 774) mention was made of a legal action in which the question of sterilization was involved. But now the medical syndical organizations of Germany—the Deutscher Aerztevereinsbund in association with the Hartmannbund—have petitioned the federal ministry of the interior to draft, at the earliest possible moment, a federal law permitting and regulating sterilization on eugenic grounds. Sterilization would of course always be contingent on the consent of the patient or his legal representative. The medical profession of Germany expressed itself as opposed to compulsory sterilization.

The subject of eugenics and sterilization is to be discussed at length at the next Deutscher Aerztetag (1933), after the preliminary work has been done.

According to existing laws, eugenic sterilization is punishable as unauthorized bodily injury. At first, an endeavor was made to have a paragraph inserted in the penal code that would provide for exceptions to the law. What is now desired is not an exception to the law but that special legislation be enacted that will legalize, for the public welfare, what has heretofore been prohibited.

Sterilization would be permitted only with the consent of the person concerned or the legal guardian, and then only in case a commission appointed by the chief authorities in each land shall give its approval. This commission would consist of a judge and two physicians, one of whom should be familiar with the "laws" affecting hereditary transmission in man. The decision of the commission would include the reasons for consenting to or refusing the sterilization. The written decision would be transmitted to the petitioner and a copy would be filed with a specially designated registrar. The physician who undertakes such an operation would also file with the registrar a short statement setting forth his reasons for the operation. Only a physician licensed to practice in Germany would be permitted to perform sterilization. The commission would impose no fees on the person to be sterilized. In the case of indigent persons, costs of the operation would be met by the welfare department. All persons having knowledge of the operation would be pledged to secrecy.

For eugenic sterilization, the persons to be considered are those suffering from hereditary mental disease, mental weakness, epilepsy or any other hereditary disease, or who have morbid hereditary predispositions, if, according to the teachings of medical science, severe bodily or mental hereditary taints are extremely likely to develop in their offspring. The legislation will not consider the social indications for sterilization, as was feared by many, nor will it deal with the medical indications, which have to do with warding off a menace to life. Sterilization on the basis of recognized medical indica-

tions is permitted by the present penal code. The bill that is being proposed has to do with the welfare of the human race, whereas the social and the medical indications concern the welfare of individuals.

Humanity as a whole suffers constantly from the fact that the procreation of persons with sound hereditary characters is not sufficient to preserve its own numbers, whereas families with severe hereditary taints are propagated without check. It is difficult to restrict the propagation of persons with unsound hereditary characters. Such restriction is absolutely necessary for economic reasons, for the number of persons with serious hereditary taints, who become criminals or a burden to the public, is increasing. A diminishing number of persons capable of earning a living has to provide for an increasing number of economic incompetents. More than \$25,000,000 annually, and probably twice that sum, if everything is considered, is needed for institutional and welfare care of incompetents, whereas persons of sound body and mind suffer in large numbers for the lack of necessities of life. The prevention of propagation among incompetents by permanent segregation in institutions is economically impossible, so that no other way is left than the elimination of their procreative power.

Heart Disease in Railway Engineers

Professor Munk of Berlin has written an article in *Soziale Medizin* on the incidence of heart disease in railway engineers, in whom it appears justified to consider heart disease as an occupational disease. He points out that 36 per cent of the deaths among railway engine crews are due to heart disease, compared with 16 per cent among the male population over 20 years of age. The average age attained by members of engine crews is 50-55 years, which is below normal. Nearly 20 per cent of the men die before reaching the highest post that the service offers. Especially striking is the great frequency of sudden death due to heart attacks in the nature of angina pectoris or coronary sclerosis. The chief factors that play a part are the constantly fixed attention of the railway engineer during his run, his great sense of responsibility and moments of intense fear, the irregular hours of the service, lack of physical exercise resulting frequently in obesity and constipation, and working under intense heat (58 C, or 136 F, at height of head).

BELGIUM

(From Our Regular Correspondent)

Feb 2, 1933

The International League Against Quackery

The Ligue internationale contre le charlatanisme, simultaneously with the Ligue belge contre le charlatanisme, held a meeting during the Brussels medical week.

Dr Brandlight, after welcoming the foreign delegates, spoke on the value of an international organization to combat quackery. The campaign should be directed on an international scale by a committee acting in collaboration with the organization and the League of Nations. Dr Joly, the French delegate, pointed out the danger of entrusting to masseurs and to nurses slight medical interventions, as it leads the way to abuses. Furthermore, by encouraging in this way the illegal practice of medicine, the physician himself becomes a violator of the law.

After a discussion in which Mr Lint of Netherlands, the president of the league, and Mr Devis (a lawyer) took part, the assembly decided to confine the crusade to the countries in which laws, customs and the conception of charlatanry are essentially the same, that is, the countries of Europe.

It was decided to publish a periodical, which will be sent to the heads of the organizations in the various countries that are

members of the International Committee. In this periodical will be reported all the judicial decisions secured against charlatans, so that it will have value as a reference work for jurists. The assembly renewed then for the year 1932-1933 the instructions as to the duties of the International Committee. Each country participating in the movement will pay dues amounting to \$20.

The topic for the next meeting, to be held at Brussels in 1933, will be "The Definition in the Various Countries of the Term Charlatanry."

Fractures of the Calcaneum

At a special session of the Societe belge de medecine et de chirurgie du travail, Professor Lenormant delivered a lecture on fractures of the calcaneum. The two groups of these fractures depending on the manner in which they are produced are (1) fractures due to tearing of the achilles tendon, and (2) fractures due to crushing, by far the more numerous. The gravity of these fractures depends on the extent to which the compact upper articular surface is driven into the spongy substance of the bone. Lenormant divides these fractures into three groups, the first not being susceptible to surgical treatment, the two others justify surgical intervention.

Lenormant emphasized the importance of the structure of the calcaneum, which consists of spongy bone reinforced by three kinds of trabeculae: the posterior, extending downward and anteroposteriorly, the anterior, extending in the reverse direction, and the third group combining the two others. Between these trabeculae, the spongy tissue is soft and friable. In fractures due to crushing, the thalamus, or the compact articular surface, is driven into the cavity below, between the bony trabeculae. The extent to which the upper articular surface is driven in is indicated by the angle of the tuberosity (Bohler). The crushing of the thalamus causes a deviation of the articular surface of the astragalus, which is forced downward and backward.

Professor Lenormant took up the treatment of these fractures. For many years a let alone policy was usually pursued, but the results were poor. Surgical treatment then began to be considered. The first operation resorted to was astragalocalcanean arthrodesis (Van Stockum). Other surgeons performed astragalectomy (Leriche and Tanton). Leriche keeps the articular surface in place with the aid of the metal devices of osteosynthesis (Dujarier's clasps or Lambotte's treatment).

The method of Lenormant and Wilmoth consists in reducing the fracture by careful removal of the fragments and by keeping the thalamus in place with the aid of bone grafts taken at first from the external malleolus and later from the internal aspect of the tibia. The foot is immobilized by means of sacks of sand and then, after the skin sutures have been removed, it is put in a plaster cast. The cavity below the thalamus is obliterated by these grafts. The results shown by Lenormant were remarkable. The calcaneum is well reconstructed. The articular deviation is minimal. Certain cases, however, present ankylosis of the calcaneo-astragaloid and the calcaneocuboid articulations, without functional impairment. The grafts are well tolerated. After a few years, they are totally absorbed and their presence can no longer be detected in roentgenograms. The functional results are good.

Death of Professor Henrijean

The death of Professor Henrijean, professor of pharmacology and therapeutics in the Societe de medecine de Liege, is announced. Since 1905, he had been a corresponding member of the Royal Academy of Medicine of Belgium. He published reports on numerous experimental researches in pharmacodynamics. In recent years, he devoted himself to a comprehensive study of the electrical manifestations of the energy of the myocardium.

MOSCOW

(From Our Regular Correspondent)

Jan 30, 1933

Congress of Surgeons of the Soviet Union

The twenty-second congress of surgeons of the Soviet Union was held in Moscow in May, 1932. About 1,800 members and guests were present. The topics on the program were (1) endemic goiter in the Union of Socialist Soviet Republics, (2) treatment of patients after operations on the gastro-intestinal tract, (3) measures for combating industrial trauma, (4) the problem of surgical cadres, and (5) blood transfusion.

Prof V S Levite compiled a geographic map showing the increase in endemic goiter in the Soviet Union. In order to combat it, prophylactic measures must be taken, sanitary and hygienic conditions improved, and small doses of iodine used.

The care of patients after operations on the gastro-intestinal tract was discussed by V M Vosnesensky, who divides it in two parts: (1) general treatment to regulate the function of all the organs and (2) special treatment for different systems and organs. The latter consists in feeding as early as possible and not forcing an early emptying of the bowels. It is well to take away bandages that restrict the respiratory movements. The co author of this paper, M A Kimbarovsky, reported that among 3,000 patients who were allowed to get out of bed early the number of cases of embolism as well as the number of postoperative pneumonias decreased.

In the discussion, Zabludovsky and Hessin did not agree with Kimbarovsky. The organization of medical care for traumatic cases was discussed by Prof V Gorinevsky, who

Percentage of Postoperative Pneumonias

	1927 1928 Before	1929 1931 After
Having patients leave bed at an early period		
Operations on the stomach	12 5	2 34
Appendectomies	5 57	0 48

said that it is necessary to render aid at the place where the trauma is received. There must be transportation to carry patients to the local trauma station, where medical help can always be obtained. The trauma station of the local hospital is the next point of treatment. The introduction of socialistic labor, the reconstruction of factories, the seven-hour day and the six day week have decreased the number of cases of traumatism.

On the fourth day of the congress the question of anaerobic infection was discussed. Prof N N Bourdenko read a paper based on his observation of 128 cases of gas gangrene and on 1,383 cases of other Russian authors. Serotherapy combined with surgery is the best treatment. Serum must be injected before gas infection develops. N M Velikanov said that gas gangrene is caused by four types of bacteria living in earth. *Clostridium welchii* is found in the wound in from 44 to 90 per cent of all cases. *Clostridium oedematiens* in from 15 to 50 per cent, *Clostridium oedematis-maligni* in from 10 to 30 per cent and *Clostridium histolyticum* in 6 per cent.

In 1929, Velikanov prepared an antigangrene serum that saved twenty-three patients among thirty-four who had gas gangrene.

The last day of the congress was devoted to the present status of the problem of blood transfusion. Prof G I Spasocutsky said that blood transfusion may be used in acute anemia, chronic anemia, infections, intoxications and constitutional diseases.

Dr V I Bratzev of Moscow demonstrated his apparatus for collective transfusion and determination of blood groups.

The Leningrad surgical clinic reported 604 cases of blood transfusion. In 343 cases, the transfusion was made by the direct method. Only one patient died of hemolysis. The influence of hemolyzed and noncompatible blood is shown by a

decrease of blood pressure and spasm of the renal vessels. The patient dies of uremia.

In the discussion, attention was called to the importance of a correct determination of the blood group as well as to the technique of transfusion. Prof E Hesse noted that the direct method gives six times fewer complications than the citrate method and spoke against the use of uremic and eclamptic blood for transfusions.

The next surgical congress of the Union of Socialist Soviet Republics will be held this year in Leningrad.

BUCHAREST

Feb 23, 1933

The Impoverished Hospitals

It is rare that one hears in the national assembly an echo of the complaints relating to the conditions under which patients languish in the hospitals. Physicians have repeatedly warned the government that the contractors threaten the hospitals with stopping supplies of drugs and food if they do not get their money, but in vain. These unbearable conditions were the subject of a speech in the national assembly by Hudita, who detailed the miserable health conditions in the county of Baia. Similar conditions prevail in several other districts. He said that in the hospitals of this county the nurses have not been paid for six months, while the officials and others have received no pay for nine months. The subsidies received during 1932 were insufficient and the hospitals are entirely impoverished. Nobody wants a contract with the hospitals, so there is no food and drugs at the disposal of the patients. Hudita appealed to the minister of health, Joanitescu, to remedy these conditions. Joanitescu found that the facts exposed by Hudita are true, but these hospitals belong to the jurisdiction of the county magistrates and he is unable to do anything. He saw on a tour of inspection that the patients had no dressing supplies at their disposal at a hospital in this county. He brought before the ministerial council the terrible conditions in the 64 state and 229 county hospitals. He demanded that 60 million lei be granted to him from the income on duties on spirits to improve conditions in the hospitals. He could get only 10 millions. He realizes that in some parts of the country hygienic conditions are the worst imaginable, but he hopes that from the revenue of the state lotteries the public health service will receive funds. Dr Lupu complained of conditions in several provincial hospitals. In the country there is, so to speak, no public health service. In the whole country there are 300 hospitals maintained by the counties, but all these are situated in towns, and there are 1,620 regional dispensaries. The minister said that the mortality rate of children and the number of tuberculosis and syphilitic patients is deplorably high. The country has no more serious problems at present than the deplorable public health conditions.

Memorial to Physicians

On the initiation of Queen Marie, a committee was formed in 1919 to provide a fund for a statue to the memory of those physicians who died at the front. In the course of thirteen years, the committee raised, together with the interests, 3,456,901 lei (nearly \$20,500). The dedication of the monument took place this month, in the presence of the king. The dedicatory speech was made by Professor Stefanescu of Galatz, vice president of the Rumanian Medical Association. The imposing statue was carved by Rafael Romanelli, the Italian sculptor. The principal figure of the monument is a woman, personifying Rumania, who is placing a wreath on the head of a physician attending a wounded soldier. The monument has been erected in the vicinity of the faculty of medicine, on the Boulevard Independentei, in which district almost all streets are named after prominent physicians.

RIO DE JANEIRO

(From Our Regular Correspondent)

Feb 1, 1933

Congenital Absence of Left Adnexa

Dr Azael Lobe reported before the Society of Medicine and Surgery of Campinas at São Paulo a case of congenital absence of the left adnexa. The patient was a woman, aged 29, mother of seven children, of whom five are living. She had always menstruated regularly. During the operation for suspension of the uterus by means of the round ligaments, the author noted the absence of the left ovary and tube. The uterus was normal, as were the round and broad ligaments. There was no trace of the left ovary, and the tube was represented by a small protuberance at the uterine cornu. In such cases the homolateral kidney, as a rule is absent. In his case he found later, on cystoscopy, that the urine issued normally from the two ureteral openings, which shows the presence of the left kidney. Reports of cases of this kind are rare.

Research on Anatomy of the Phrenic Nerve

Dr Renato Locchi has made a systematic study on a series of white, Negro and half-breed cadavers in order to determine whether there are racial differences in the number and the location of the phrenic nerve and of the so-called accessory phrenic nerves. He has dissected 100 phrenic nerves. He concludes that (1) the third cervical root contributes more to the phrenic nerve in the Negro and the half-breed (50 per cent) than in the white, the so-called cranial migration of the phrenic nerve appearing to be more accentuated in their case, (2) in the material examined, the accessory phrenic nerves were frequent (71 per cent) and came in 52 per cent of the cases from the nerve to the subclavian muscle.

Lesions in Exanthematous Typhus

Dr Moacyr Amorim described previously the lesions he found in a necropsy in a case of typhus which, as in most cases, consisted of a hemorrhagic disturbance with septic infarcts of various viscera. He found in the cerebellum a few granulomatous nodules similar to those described by Popoff and Fraenkel, he also found the lesion described by Spielmeyer, which consisted of arborescent hyperplasia of the microglia, especially in the molecular layer. He says that the coexistence of these lesions with the usual lesions in other viscera is characteristic of the pathology of this disease. His communication was illustrated with projections of microscopic slides.

The Alkali Reserve in São Paulo

Dr Dutra de Oliveira has studied with the method of Van Slyke and Cullen the alkali reserve of the plasma in persons living in tropical climates. He estimated with the apparatus of Bailey the amount of carbon dioxide and of oxygen in the alveolar air. He found that the average alkali reserve of males is 57.8 per cent in São Paulo and 54.9 per cent in Rio de Janeiro, and of females 50.3 per cent in Rio de Janeiro and 53.5 per cent in São Paulo. These data do not agree with those obtained by Sundstroem in Australia, where the average was 64 per cent. In São Paulo the amount of alveolar carbon dioxide was 5.02 per cent, and of oxygen 14.7 per cent. On this point there is some relation with the average of Sundstroem, which was 5.12 per cent for males and 5.24 for females.

Postvaccinal Encephalitis

Dr Joaquim Pennino presented before his colleagues two cases of postvaccinal myelo-encephalitis. He compared the location and the nature of the lesions with those due to encephalitis. In giving the probable causes, he mentioned the following factors: (1) myelomic immaturity of the nervous system before the age of 3 years, (2) instability of the endocrine neurovegetative nervous system, making of the child in the first year of its life a megalosplanchnic biotype of low immunity, (3)

retardation, at times hardly apparent, of maturity of the nervous fibers, (4) neuropathic stigmas. These factors allow the vaccine virus to attack the central nervous system. The author advises the following rules for vaccination: (1) examination of the neuromuscular system, especially with regard to maturity, (2) production of not more than one pustule before the age of 3 years, (3) scarification as superficially as possible, (4) abstention from vaccination during the summer, whenever possible, because in this season the immunity of the child is low.

Perforation of the Stomach in Blastomycosis

Drs Lourival Santos and Floriano de Almeida state that blastomycosis in São Paulo is generally produced by *Paracoccidioides brasiliensis*. They cite a case of blastomycosis with perforation of the stomach due to a suppurating lymph node which produced necrosis of the serous and muscular tunics and subsequent perforation of the mucosa.

Experiments on Diabetes with Diathermy of the Pancreas

After long experimentation, Prof Alexander Korányi and Dr Zoltan Rausch succeeded in reducing the blood sugar in healthy subjects and also in diabetic patients by means of diathermy of the pancreas. The degree of reduction is slight as yet but is nevertheless encouraging. In cases of mild diabetes, the systematic use of diathermy of the pancreas with sittings of half an hour to an hour before the principal meals improved carbohydrate tolerance. In rather severe cases of diabetes, diathermy of the pancreas had not the slightest result, so that Professor Korányi refrained from repeating the experiments on such patients. Under the action of diathermy, the insulin production of the pancreas could be increased and, hand in hand with this, the glycolytic power of the blood, Korányi and Rausch concluded that, if there exists a sufficient quantity of interstitial cells, diathermy of the pancreas is likely to act favorably on diabetes and on all its symptoms, while if the reduction of the islands of Langerhans is of a great degree, caution must be observed, for there is the possibility of the exhaustion of the secretory function.

Pathetic Story of a University Professor

Dr Imre Basch, late director of the St. Stephen Hospital in Budapest, became ill some months ago with pain in his chest and difficult breathing. His physician friends assured him that his condition was not grave. He felt that his friends concealed the truth, and he tried a pious fraud. He wrote to Professor Finsterer in Vienna that a patient of his would call on him, whom he suspected to have cancer. He called on the professor, giving a false name. Finsterer made a thorough examination and said that he would give instructions as to treatment to his attending physician, Professor Basch of Budapest. In this letter he reported that his patient had cancer of the lungs and in his opinion had about two months to live. Instead of counting the days, Basch recalled the case of the bookkeeper in "Grand Hotel," who, having been told that he would die shortly, cast away in his last months all that he had saved during his lifetime. Professor Basch acted similarly. The temperate bachelor who had devoted all his energy to the furthering of medical science, threw himself into the night life. Although he had never tasted champagne, he began to indulge in alcohol. He danced into the night on that thin rope which separated him from death, said his friend at the funeral. This revelry hastened his death, which occurred last week. Professor Basch was a prolific writer on dermatology and venerology. His treatises would form volumes, had he published them in book form. As a teacher at the university he was foremost, as proved by the great number of his pupils.

Marriages

- BERNARD LAURISTON HARDIN, JR., Washington, D C, to Miss Dorcas Fletcher Hull at Pittsfield, Mass, March 11
HARRY BRYANT SMITH, Hartford, Conn., to Miss Isabel Frances Eveleth of Windsor, February 22
CHARLES BERKOWITZ, Chicago, to Miss Mary Aberbom of Winnipeg, Manit., Canada, March 19
FRANKLIN C BEEKS to Miss Katherine Bannon, both of Portsmouth, Ohio, recently
ERVIN B WALLACE, Baltimore, to Miss Helen Hauptert, recently

Deaths

John Francis Herrick ♂ Ottumwa, Iowa, Keokuk (Iowa) Medical College, 1891, member of the House of Delegates of the American Medical Association in 1931, past president of the Iowa State Medical Society, fellow of the American College of Surgeons, member of the Radiological Society of North America and the American College of Radiology, served during the World War, on the staffs of St Joseph and Ottumwa hospitals, aged 68, died, February 23

Douglas Hunt Stewart ♂ New York, College of Physicians and Surgeons in the City of New York, Medical Department of Columbia College, 1882, fellow of the American College of Surgeons, member of the American Urological Association, for many years on the staff of the Knickerbocker Hospital, aged 72, died, March 15, of cerebral hemorrhage and arteriosclerosis

Carl Otto Fischer, Brooklyn, Long Island College Hospital, Brooklyn 1916, member of the Medical Society of the State of New York, fellow of the American College of Surgeons, served during the World War, attending obstetrician to the Wyckoff Heights Hospital and the Bushwick Hospital, aged 45, died suddenly, March 9, of pulmonary embolism

William Thomas Gott, Crawfordsville, Ind., Eclectic Medical Institute, Cincinnati, 1878, member of the Indiana State Medical Association, since 1897 member, past president and secretary of the Indiana Board of Medical Registration and Examination, on the staff of the Culver Hospital, aged 77, died, February 24, of cerebral hemorrhage.

Ralph Waldo Hissem ♂ Wichita, Kan., University of Kansas School of Medicine, Kansas City, 1911, member of the American Urological Association, fellow of the American College of Surgeons, served during the World War, urologist to the Wichita Hospital, aged 47, died, February 27, of injuries received in an automobile accident

Harry French Hoyle ♂ Newburgh, N Y, Jefferson Medical College of Philadelphia, 1915, member of the Associated Anesthetists of the United States and Canada, past president of the Orange County Medical Society, aged 51, on the staff of St Luke's Hospital, where he died, February 28, of cerebral hemorrhage

Elston Hunt Bergen, Princeton N J, College of Physicians and Surgeons in the City of New York, Medical Department of Columbia College, New York 1877, bank president, formerly member of the board of health, on the staff of the Princeton Hospital, aged 81, died, March 8, of bronchopneumonia.

Bernard F Garnitz, Chicago, Loyola University School of Medicine, Chicago, 1921 member of the Illinois State Medical Society, aged 41, on the staff of the Evangelical Hospital, where he died, March 11, as the result of gunshot wounds inflicted by bandits, when he was lured by a false emergency call

Julius Theodore Haller ♂ Davenport Iowa Johns Hopkins University School of Medicine Baltimore, 1905 fellow of the American College of Surgeons on the staff of St Luke's Hospital, aged 54, died, February 28 of burns received when his automobile caught fire after plunging into a ditch

Harry Greensfelder, St. Louis, St. Louis University School of Medicine, 1903, member of the Missouri State Medical Association, veteran of the Spanish-American War, aged 54, died, February 26, in the Barnes Hospital, as the result of an injury received in a fall

Charles Lawrence Bradshaw, Crownsville, Md., Medical College of Virginia, Richmond, 1912, member of the Medical Society of Virginia, served during the World War, aged 44, on the staff of the Crownsville State Hospital, where he died, February 22, of erysipelas

Richard Gerstell, Keyser, W Va, University of Maryland School of Medicine, Baltimore, 1873, bank president, aged 81, died, January 13, in the Memorial Hospital, Cumberland, Md, of arteriosclerosis, hypertrophy of the prostate and bronchopneumonia.

John Carlton Brown, Williamsport, Pa, University of Buffalo School of Medicine, 1889, member of the Medical Society of the State of Pennsylvania, for many years on the staff of the Williamsport Hospital, aged 68, died, February 13, of heart disease

Archibald Daven Galloway ♂ Barron, Wis, Bennett College of Eclectic Medicine and Surgery, Chicago, 1908, member of the state board of medical examiners, part owner of the Riverside Hospital, aged 47, died suddenly, February 23, of heart disease.

Charles Carrell Krusen, Woodbury, N J, Hahnemann Medical College and Hospital of Philadelphia, 1921, county coroner, on the staff of the Brewer Hospital, aged 38, died, February 27, in the Hahnemann Hospital, Philadelphia, of heart disease.

Charles Wesley Thompson, Meadville, Pa., Medical Department of Western Reserve University, Cleveland, 1882, member of the Medical Society of the State of Pennsylvania, aged 74, died, Nov 21, 1932, of carcinoma of the esophagus

Michel Delphis Brochu, Quebec, Que, Canada, Laval University Faculty of Medicine, 1876, emeritus professor of medicine at his alma mater, formerly superintendent of the Beauport (Que) Insane Asylum, aged 80, died, March 12

George Edward Delaney, Galveston, Texas, University of Texas School of Medicine, Galveston, 1896, member of the State Medical Association of Texas, aged 58, died, February 20, in the John Sealy Hospital, of cerebral thrombosis

John H Rehberger, Baltimore, University of Maryland School of Medicine, Baltimore, 1873, member of the Medical and Chirurgical Faculty of Maryland, aged 82, died, January 22, of arteriosclerosis and chronic myocarditis

Walter Fisher Carstens, New Iberia, La, Medical Department of the Tulane University of Louisiana, New Orleans, 1901, health officer of New Iberia, aged 57, died, February 19, of cerebral hemorrhage

Mary West Niles, Pasadena, Calif, Woman's Medical College of the New York Infirmary for Women and Children, 1882, formerly a medical missionary, aged 79, died, February 4, of influenza and bronchopneumonia

Mell Aycock ♂ Atlanta, Ga, Emory University School of Medicine, Atlanta, 1917, served during the World War, on the staff of St Joseph's Infirmary, aged 39, died, February 25, of carcinoma of the liver

Henry Muetze, St. Louis Missouri Medical College, St. Louis, 1891, member of the Missouri State Medical Association, aged 69, died, January 25, in the Missouri Baptist Hospital, of cerebral hemorrhage.

Henry Joseph Keaney ♂ Everett Mass Baltimore Medical College, 1901, served during the World War, on the staff of the Whidden Memorial Hospital, aged 54, died suddenly, March 1, of angina pectoris

Frederic W Kuechler ♂ Newton, Ill, Medical College of Indiana, Indianapolis, 1893, formerly county coroner, member of the state legislature and bank president, aged 56, died, February 25, of uremia.

George F Cocker ♂ New Orleans, Medical Department of the Tulane University of Louisiana, New Orleans, 1898, aged 67, died, February 12, of cerebral hemorrhage, arteriosclerosis and nephritis

Harry W Subera, Sioux Falls, S D, College of Physicians and Surgeons, Keokuk, Iowa, 1884 member of the South Dakota State Medical Association, aged 85, died, January 28, of influenza.

Albert Herman Hundertmark, Los Angeles, Bennett Medical College, Chicago, 1913, member of the Illinois State Medical Society served during the World War, aged 44, died, February 10

George Howard Fay ♂ Auburn, Calif, Cooper Medical College, San Francisco, 1902, formerly secretary of the Placer County Medical Society, aged 68, died, February 24, of cerebral embolism

♂ Indicates Fellow of the American Medical Association

Samuel A V Christophine, Attapulcus, Ga., Southern Medical College, Atlanta, 1898, member of the Medical Association of Georgia, aged 64, died suddenly, February 22, of heart disease

William Stuart Grimes, East Detroit, Mich., University of Buffalo School of Medicine, 1901, aged 62, died, February 24, in St Joseph's Hospital, Mount Clemens, of gastric hemorrhage

Edward Haynes Woodruff, San Diego, Calif., McGill University Faculty of Medicine, Montreal, Que., Canada, 1890, aged 75, died, January 16, of chronic nephritis and heart disease

Adam Rush King, Fort Worth, Texas, Hospital College of Medicine, Louisville, Ky., 1905, member of the State Medical Association of Texas, aged 55, died, February 14, of heart disease

Gilbert Clement McMaster ♂ Pittsburgh, Western Pennsylvania Medical College Pittsburgh, 1903, served during the World War, aged 57, died, February 7, of coronary disease

John Rollin Shultz ♂ Charleston, W Va., Medical College of Virginia, Richmond, 1918, on the staff of the Mountain State Hospital, aged 42, died, February 6, in a local hospital

Jay Wesley Hamilton, Jacksonville, Ill., Missouri Medical College, St. Louis, 1880, on the staff of the Illinois State Hospital, aged 75, died, February 20, of lobar pneumonia

James Edward O'Donohue, Floral Park, N Y., Long Island College Hospital, Brooklyn, 1885, aged 72, died, January 23, of chronic interstitial nephritis and uremia

Seth Andrew Light ♂ Lebanon, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1904, aged 58, died, February 10, of coronary thrombosis and nephritis

Margaret M Morris, Los Angeles, University of Southern California College of Medicine, Los Angeles, 1907, aged 62, died, January 12, of carcinoma of the stomach

John Henry Riley, Adams, Mass., University of Vermont College of Medicine, Burlington, 1885, aged 80, died, February 6, of hemorrhage of the cerebral artery

William H Oliver ♂ Bryan, Texas, Medical Department of the Tulane University of Louisiana, New Orleans, 1890, aged 63, died, February 7, of heart disease

George P Rishel, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1883, aged 80, died, January 4, of carcinoma of the stomach

Frederick Hutchison ♂ Aldie, Va., Washington University School of Medicine, Baltimore, 1876, aged 80, died, February 20, of cerebral hemorrhage

Morris Winston Gibbs, Lynchburg, Va., Medical College of Virginia, Richmond, 1912, aged 54, died, January 28, in Bellevue, of cerebral hemorrhage

Joseph Pendleton Stovall, Sardis, Miss., Memphis (Tenn.) Hospital Medical College, 1883, aged 76, died, February 15, of cerebral hemorrhage

W Worley Damron, Carbondale, Ill., St. Louis College of Physicians and Surgeons, 1904, aged 53, was killed, Dec 23, 1932, when struck by a train

John Wesley Jennings, Mohawk, N Y., Albany (N Y.) Medical College, 1896, aged 65, died, February 14, of bronchopneumonia and undulant fever

Emily Irvine Smith, Windsor, Ont., Canada, University of Toronto Faculty of Medicine, 1890, aged 64, died, Dec 20, 1932, of pneumonia

Samuel E Reynolds, Elizabethton, Tenn., Eclectic Medical Institute, Cincinnati, 1891, aged 69, died, February 10, of cerebral hemorrhage

Hugo Sittel Weusthoff, Cranford, N J., Miami Medical College, Cincinnati, 1880, aged 73, died, Dec 30, 1932, of lobar pneumonia

Edwin Webster Shearburn, Fairbury, Neb., Chicago Homeopathic Medical College, 1902, aged 70, died suddenly, Dec 11, 1932

Frederick T Foard, Hickory, N C., Louisville (Ky.) Medical College, 1886, aged 76, died, February 4, of cerebral hemorrhage

Edward G Stout, Earlville, N Y., Albany Medical College, 1896, aged 60, was found dead, February 15, of angina pectoris

Wilhelm Becker, Milwaukee, Milwaukee Medical College, 1897, aged 62, died, February 17, of heart disease

Gus H Covington, Wadesboro, Ky. (licensed, Kentucky, 1893), aged 89, died, February 25, of pneumonia

METHYLENE BLUE AND CYANIDE POISONING

To the Editor —Attention has recently been drawn (Brooks, Matilda M. *Am J Physiol* **102** 145 [Oct] 1932 Geiger, J C. *THE JOURNAL*, Dec 3, 1932, p 1944 Hanzlik, P J, *ibid*, February 4, p 357 Eddy, N B. *J Pharmacol & Exper Therap* **41** 449 [April] 1931 Hug, Enrique. *Compt rend Soc de biol* **111** 519, 1932) to the earlier observation (Sahlin, B. *Skandinav Arch f Physiol* **47** 284, 1925) that the injection of methylene blue antagonizes the toxicity of hydrocyanic acid administered to animals and man. The explanation of this protective action of the dye is of interest from several points of view: its bearing on the mechanism of tissue respiration, the possibility that other more effective antidotal agents may be found, and the limit to which protection against hydrocyanic acid poisoning may be expected from the dye and similarly acting substances. The purpose of this communication is to point out a few facts which bear on these questions.

Sahlin, Eddy and Brooks have expressed the view that the dye acts in overcoming cyanide poisoning by providing a substitute for the normal cellular catalysts of respiration which are inactivated by cyanide. Although this is a natural inference, in view of the known effect of methylene blue in partially restoring the respiration of certain hydrocyanic acid poisoned tissue or cell suspensions in vitro, it can be easily shown that a quite different explanation is the correct one as regards the antidotal action of the dye toward hydrocyanic acid in intact animals. It is known that methylene blue both in vivo (Combemale, M. *Compt rend Soc de biol* **43** 300, 1891) and in vitro (Wendel, W B. *Proc Soc Exper Biol & Med* **27** 624 [April] 1930 Wendel, W B, and Shaffer, P A. *J Biol Chem* **87** 11 [June] 1930 Warburg, O, Kubowitz, F, and Christian, W. *Biochem Ztschr* **227** 245, 1930) catalytically converts hemoglobin into methemoglobin, and that methemoglobin forms with hydrocyanic acid an unusually stable compound, cyanmethemoglobin. So firm is this union that hydrocyanic acid is removed with difficulty if at all by a vacuum, and methemoglobin may be used as an effective reagent for absorbing hydrocyanic acid from exceedingly dilute solutions or gases. From these facts it would seem to follow that formation of methemoglobin by the injected methylene blue leads to fixation of hydrocyanic acid as cyanmethemoglobin within the blood cell, whether the hydrocyanic acid enters the blood stream by absorption from the lungs, the alimentary tract, or the tissues into which it might have penetrated before the dye has been injected. If this is the correct explanation, a like or better protection from hydrocyanic acid poisoning should be afforded by the injection of methemoglobin alone, or by other agents which form methemoglobin more rapidly.

Experiments that confirm these expectations are to be reported before the American Society of Biological Chemists at its April meeting. In the meantime a paper has just appeared by Hug (*Compt rend Soc de biol* **112** 511, 1933) in which the same facts are recorded and the same conclusions are drawn. It is therefore timely that the results that Hug and I have obtained be brought to the attention of those interested in hydrocyanic acid poisoning.

The reinjection (intravenously) into dogs of the cells from 20 cc of blood per kilogram of body weight, the hemoglobin of which has been converted to methemoglobin (by amyl nitrite, the excess nitrite being removed) effectively protects the animals from the toxic effects of a lethal dose of hydrocyanic acid. Also, the same volume of methemoglobin cells when injected into animals approaching death from a lethal dose of hydrocyanic acid rapidly revives the animals.

Hug finds that sodium nitrite (which is well known to form methemoglobin) is much more effective than methylene blue in protecting from cyanide. And in his most recent paper he finds that pyrogallol, pyrocatechol and phenylhydrazine have a similar effect.

As the antidotal action depends on conversion of oxygen-carrying blood pigment (hemoglobin) into nonfunctional pigment (cyanmethemoglobin), it follows that the successful use of methylene blue, or any other substance which acts in a similar manner, is limited by the extent to which this transformation is compatible with life. Probably not more than one half to two thirds of the hemoglobin can be spared under such circumstances without leading to asphyxia from insufficient oxygen transport. Since the normal hemoglobin content of dogs or man is about 0.7 to 0.8 millimols (as oxygen capacity) per kilogram of body weight, four lethal doses of hydrocyanic acid (0.44 millimols per kilogram, according to Hug) would inactivate about 60 per cent of the total blood pigment. As a matter of fact, this is the maximum dose from which Hug finds nitrite to afford protection. Analysis of the available data on the case of cyanide poisoning in man that was successfully treated with methylene blue (Geiger) serves as a further illustration. The amount of cyanide (potassium cyanide) absorbed (1 Gm less 0.05 Gm removed from the stomach) probably inactivated hemoglobin equivalent to about 16 liters of blood, or perhaps one fourth to one third of the total. Such a loss of oxygen-carrying capacity need not be serious. The absorption, however, of 2 Gm of potassium cyanide probably, and the absorption of 3 Gm almost certainly, would have been fatal in spite of the administration of methylene blue.

It appears to follow from the foregoing considerations that a possible protective action of methylene blue against the effects of hydrocyanic acid on the tissues is not susceptible of demonstration with the intact animal, because the animal will die from loss of functional hemoglobin before there is a surplus of hydrocyanic acid present to inactivate the tissue catalysts.

WILLIAM B WENDEL, PH D, St Louis
Instructor in Biological Chemistry, Washington
University School of Medicine

THE MATERNITY WARD OF THE GENERAL HOSPITAL

To the Editor—As honest doctors we are our own severest critics. Dr DeLee's recommendations are sound but temporarily impractical.

Here are some figures from Detroit, which no doubt are being duplicated all over the country. The maternal mortality from 1928 through 1932 was 65 per thousand live births. Contrary to European statistics, this includes deaths from criminal abortions. In 1929, 33 per cent of all deaths and 59 per cent of septic deaths were due to abortions. These cannot be laid at the door of the obstetrician. Correcting the records for this inclusion reduces the rate to about 45.

During this period there were 8000 deliveries in Harper Hospital with a death rate of 29, and 10500 births in Providence Hospital with a mortality of 37. The figures for this city at large include these cases.

Two other facts are noteworthy. 1 The most seriously ill patients are sent to the hospital and among them the death rate is high. 2 Hospital cases are subject to searching inquiry by the medical staff, and hence their statistics are accurate. There is not such an accurate check up on the causes of death in home deliveries.

Providence Hospital caters to the general practitioner and receives many complicated cases. Harper Hospital is patronized more by the specialist and draws a more carefully selected class of patients. Both institutions have mortality rates well below

that of the district. Both are general hospitals subject to the disadvantages claimed by Dr DeLee.

Great movements have intangible reasons unexplainable by cold figures. Hospitalization of maternity cases is due to many factors, including (1) much better anesthesia and (2) correct surgical repair of lacerations.

Hospitals need not be "cesspools of infection." Puerperal sepsis (not including septic abortions), accounting as it does for only 25 per cent of all deaths in the Detroit area, is not as great a danger as one would gather from Dr DeLee's article. Add to his remedies (1) better instructions in obstetrics both for undergraduates and for postgraduates, (2) elevation of the obstetric division of the hospital to a plane equal to that of medicine and surgery, (3) education of the public to the fact that having a baby merits as much thought as being operated on for appendicitis or gallstones.

HAROLD HENDERSON, M D, Detroit

"ERADICATING BOVINE TUBERCULOSIS"

To the Editor—THE JOURNAL of February 18 contains an editorial called "Eradicating Bovine Tuberculosis" which has some queer statements in it. What is meant by "It has also been demonstrated that the usual form which tuberculosis of the bovine type takes in the human patient is the nontuberculous, especially bone and gland"?

Your writer has evidently not read correctly the classic article by Koch published in 1882. A few quotations from it will suffice. "It became evident that, just as the picture of the disease is the same, whether produced by all the enumerated different substances, so do the bacillary cultures obtained from the lungs of apes, miliary tubercles from the brain and enumerated by him in a preceding paragraph included tubercles from the lungs of human beings, caseous materials from phthisical lungs, and nodules from the lungs and the peritoneum of cattle with present in various tuberculous processes cannot be doubted" (Human lungs with miliary tuberculosis, caseous pneumonia, sucht in cattle). "Miliary tuberculosis, caseous pneumonia, perlsucht in cattle, spontaneous and infectious tuberculosis, animals, must, according to my investigations, be declared identical" (translation of "Die Aetiologie der Tuberkulose," by Dr and Mrs Max Pinner, N T A, 1932).

Koch said that though he thought there might be some differences, he had been unable to detect them. Theobald Smith, in 1896 (not 1898, as given by your writer) first showed that there was a distinct difference between the human and the bovine organisms. His second paper appeared in 1898.

The first scientific proof that the bovine tubercle bacillus was dangerous to man was given from the Laboratory of the State Live Stock Sanitary Board of Pennsylvania, April 24, 1902. The work by Park and Krumwiede did not appear for some eight years after and was stimulated by Koch's second statement made at a congress in this country, that the bovine tubercle bacillus did not cause pulmonary tuberculosis in human beings. Your writer has also apparently never heard of the work of the Royal Commission on Tuberculosis in England, or the Imperial Commission in Germany.

MAZACK P RAVENEL, M D, Columbia, Mo

COMMENT—Dr Ravenel's first criticism is of the statement "It has also been demonstrated that the usual form which tuberculosis of the bovine type takes in the human patient is the nontuberculous especially bone and gland." In this sentence the nontuberculous should have read nonpulmonary, this being an error in copy which was not detected during revision.

The historical references relating to the development of our knowledge of tuberculosis are incidental to the main purpose of the editorial. It is, of course, correct that Koch's original work regarded the bovine and human forms as identical, but later he did hold that the germs were of different type and also that the bovine bacillus was incapable of infecting man. A statement to this effect was published in *THE JOURNAL*, Feb 20, 1926, and was apparently not challenged at that time. In the historical references it was not deemed necessary to cite all the supporting evidence, such as the work of the Royal Commission on Tuberculosis, in England, or the Imperial Commission, in Germany.

While Dr Ravenel's criticisms are correct, it does not appear that they affect the essential correctness of the facts presented in the editorial as a basis for the argument that bovine tuberculosis requires eradication.—Ed

THE FACTS ABOUT A REPRESENTATIVE SOUTHERN COUNTY

To the Editor—Many years ago I heard a rather intelligent chap say that there are three degrees of untruth: lies, damned lies and statistics. This remark has been recalled a number of times lately, when reading matter relating to the Report of the Committee on the Costs of Medical Care, and expresses excellently my opinion of the whole proceedings.

It is extremely easy to collect a set of figures that can be interpreted in any way that any one of a dozen people wish to do. The committee (save the mark) has turned out a striking example.

An interesting illustration has just reached me. Surveys of the Medical Facilities in Three Representative Southern Counties, one being Lee County, Mississippi. This "representative" county, according to the information given in the survey, is "comparatively small" and its "per capita spendable money income" is 11 per cent plus less than the average for the state. How, then, can it be classed as representative?

It spends \$11.14 per capita for medical care, and out of this it supports a thirty-five bed hospital and some thirty-eight rattling good doctors, many of whom I know personally.

For fourteen years it has had a full time health department, which now carries five full time employees. "Some of the smaller towns have local physicians who serve as health officers (without salary or specific duties)." In other words, they do what is needed without any higher-up specifying what they are to do.

The survey says "The prevalence of malaria is a serious problem in the rural areas of this county." Its health officer says "Within recent years numerous drainage problems resulted in marked improvement of health conditions, especially in the prevention of malaria."

The survey says "Cotton is the chief product the money derived from the sale of cotton is received only once a year consequently many particularly of the tenant farmer class are virtually without cash income for the major part of the year." The health officer says "Most every farmer owns high-bred Jersey cattle, many of which are registered, and the production of dairy products has increased very rapidly for the past few years. Milk and cream routes are established by or near most every farm in the county, and deliver these products at Tupelo. The growing of strawberries and truck farming is proving very valuable in some sections of the county."

With these errors as to conditions in the county it is not surprising that one finds other errors when it comes to a consideration of medical conditions.

The survey says "In the absence of adequate personnel for all phases of health department work, school hygiene, immunization, and a general program of health education have been

considered of greater immediate importance than maternal, infant, and preschool hygiene." The inference is that the latter have been neglected. The report of the health officer states that clinics are held in different communities throughout the county regularly each month and that midwives are required to bring their cases to the clinic for general examination. Wassermann tests are made, and urinalyses made regularly every two weeks. Home visits are made by the nurses. Pre-school clinics have been held throughout the county for both white and Negro children during the summer and fall months of each year. The attendance in general has been good. The quotations from the county health officer are taken from his report to the state board of health and the legislature and cover a period of two years ended July 1, 1931.

All of which would go to show that the people of Lee County are not in such an awful fix after all, even if they do not spend per capita as much for medical care as the executive committee of the committee considers a safe minimum.

E F HOWARD, M D, Vicksburg, Miss

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

URETHRITIS OF ALLERGIC ORIGIN

To the Editor—In *Queries and Minor Notes* (*THE JOURNAL*, February 18) is a discussion of nongonorrheal urethritis. I have found a number of these cases to be due to food allergy, idiosyncrasy or whatever such reactions should be called. I have had three within the past year due to the drinking of tomato juice in excess, another from oranges and apples, and one from wheat bread and strawberries. One of the tomato patients tried it out on three separate occasions at intervals of two months and each time the discharge returned, to stop in a few days after discontinuance of the drink. He has never had gonorrhea. However, he gets urticaria and asthma from eating pork sausage. Most of the cases I have seen are in young men who state that they have not had gonorrhea. Certainly no gonococci can be found in the discharge, which consists mostly of mucus with a moderate amount of pus cells. The prostates are larger than normal and boggy at the time the discharge is present. I suspect many of the cases of long drawn out thin discharges following gonorrheal infection are due to this idiosyncrasy to food rather than to any residual inflammation. It will well repay investigating this angle of these cases. I always read the department of *Queries and Minor Notes* first. There is a lot of good stuff there for general practitioners.

M D

ANSWER—Food allergy is a distinct cause of irritable bladder. Resistance is low in a patient suffering from intrinsic allergy. It is in line with good thought to believe that a slight catarrhal discharge with or without superimposed nongonorrheal infection could complicate chronic allergy.

It is important to remember that food allergy can give rise to mucous membrane edema, congestion, and mucous discharge and smooth muscle spasm in any part of the body, and that the bladder and urethra and even the ureters are not exempt. Perennial hay fever due to food sensitization producing nasal congestion, occlusion and mucoid discharge exemplifies such reactions in the nasal tissues. Mucous colitis is frequently due to food allergy, and recently leukorrhea has been described as one of the manifestations of uterine allergy. Bladder allergy was originally described by Duke and corroborated in a recent monograph on food allergy. The presence of eosinophilic leukocytes in the secretion would point toward allergy. The cystoscopic appearance of the bladder would be of interest, and such examinations should rule out definite pathologic changes. Hivelike swellings in the bladder mucosa have been seen. It may be mentioned that burning in the bladder and urethra often is extremely severe and persistent in bladder allergy, and spasms and pain in the urogenital tissues are frequently present. Excoriation of the vulval tissues extending to the adjacent skin has been reported, but similar lesions in the male tissues have not been recorded. In all problems of allergy especially those due to food, it is important to remember that many of the symptoms may be similar to those caused by infections and other disease types, though allergy may coexist with such conditions.

Thus this diagnosis of allergic urethritis is probably correct and should be kept in mind by physicians in handling urologic

problems Allergy should be suspected especially in patients who have a personal or family history of hay fever, asthma, eczema, urticaria, angioneurotic edema, migraine or abdominal allergy. Histories of definite food dislikes or idiosyncrasies may or may not be elicited. Skin tests may indicate the causative foods but are frequently negative, especially in adults. Intradermal tests with active dependable sterile extracts are more valuable than are scratch tests. However, such reactions are often nonspecific and hard to interpret and their etiologic significance must be checked by actual food trial. "Elimination diets" modified by a history of food idiosyncrasies and skin reactions are of value in the determination of food allergies, particularly when diets based on reacting foods do not produce relief or when skin reactions are negative in a patient suspected of food allergy. The principles underlying these diets and the importance of absolute cooperation of the patient must be realized by physicians who use them.

SEBORRHEIC DERMATITIS PSORIASIS OF SCALP OR PITYRIASIS RUBRA PILARIS

To the Editor—A woman, aged 52, past the climacteric, well nourished began to be troubled about three years ago with a disorder of the scalp. There has been no loss of hair. The lesions appear in isolated spots with a desquamation and under these scales they are hyperemic and dry. The scales are white and may be small or enlarged flakes. The condition appears on the anterior hair border or on the superior surface of the scalp. The patient is constantly annoyed by the desquamation. There is no particular itching. It will almost clear up at times and then comes back. I have tried many lotions and shampoos and oils. The one treatment that has seemed to do the most good is a strong exposure to ultraviolet rays. I will appreciate any suggestion in the way of diagnosis and treatment.

E B MINOR, M D, Traverse City, Mich

ANSWER—Seborrheic dermatitis and psoriasis are the common diseases causing such involvement of the scalp. Pityriasis rubra pilaris may begin in the scalp but it begins usually at an earlier age, seldom remains so long confined to the scalp, and produces greasy scales, which mat together to form thick masses.

If this is seborrheic dermatitis, it is an unusual case because of the absence of itching or any tendency to loss of hair in three years, and the large dry flakes that form.

Psoriasis of the scalp may appear and persist for some time without appearing on the glabrous skin. It causes no itching or loss of hair and involves the frontal hair border as described. The patches are sharply circumscribed and tend to form heaped up scales if not constantly treated.

Either of these diseases might yield to ultraviolet rays but the readiness with which this case yields is unusual for psoriasis.

So long as this ready response to ultraviolet radiation continues, no other form of therapy can be suggested that is so clean and pleasant to use. After the scales have cleared up as a response to this treatment, a stimulating lotion such as

Corrosive mercuric chloride.	Gm or Cc.
Resorcinol monoacetate	0.2 to 0.4
Castor oil	60
Spirit of formic acid	60
Compound spirit of myrcia	20.0
Alcohol	30.0
Distilled water	30.0
	to make 120.0

may be used, shaken and applied with a medicine dropper, then well rubbed into the scalp. Daily, vigorous brushing with a stiff bristle brush is recommended. The castor oil may be omitted if the hair does not need it and the corrosive mercuric chloride increased or decreased as judged best. Frequent use of a tar shampoo, for instance,

Coal tar solution	Gm or Cc.
Liniment of soft soap	3.6
	to make 120.0

may be recommended

IMMUNIZATION AGAINST SCARLET FEVER

To the Editor—Will you be kind enough to give me any information regarding E. R. Squibb and Son's product for scarlet fever immunization treatment? How long does this last? Are there any reactions? Is it safe to use on children of all ages? Are there any contraindications? Should they be tested before administration or after? Is it recommended by any state health department? Please give me any further facts that you may have. Please omit name.

M D, Illinois.

ANSWER—It has been found that active immunization with graduated doses of scarlet fever toxin, if carried to the point of an entirely negative skin test, may be expected to last for a period of at least four to five years in more than 90 per cent of the persons thus immunized. Statistics from groups retested at longer intervals are not yet available.

There are reactions during the course of active immunization. These reactions may consist of local redness and swellings, or in more highly susceptible persons there may be general reac-

tions associated with fever, nausea and rash which usually disappear within forty-eight hours.

According to the information thus far available, it is safe to immunize children of all ages, including infants.

Exceptional individuals are sensitive to broth and in these individuals urticaria may develop within a few minutes after injection of any preparation containing broth, including scarlet fever toxin and diphtheria toxoid. The development of urticaria in such individuals may usually be prevented by injection of 0.2 cc of a 1:1,000 solution of epinephrine hydrochloride taken up in the same syringe with the immunizing dose.

It is advisable to make tests for susceptibility to scarlet fever before immunizing against the disease, because many persons are spontaneously immune to the disease and do not require immunization. Retests should always be made after immunization.

Scarlet fever immunization is employed by a number of the state health departments, including Illinois, Michigan and Kentucky.

These answers are made on the assumption that the questions concern scarlet fever toxin for active immunization rather than scarlet fever antitoxin for temporary passive protection, and they apply to the E. R. Squibb & Sons product as well as to the other commercial products now on the market in the United States.

EFFECTS OF COLD QUARTZ ULTRAVIOLET RAY ON EYE

To the Editor—Would it be possible for a patient to get permanent injury to the eyes, with the cold ray ultraviolet one minute at 24 inches? The eyes were unprotected but did not look directly at the light all the time. There was some pain and burning four or five hours later, but the whole condition apparently cleared up within two or three days. Five weeks later the patient began complaining of weak eyes and one physician attributes this to the ultraviolet. Is it possible that the patient has received a permanent injury? Please omit name and address.

M D, Kansas

ANSWER—There are two types of cold quartz ultraviolet generators: the official applicator and the grid type for body radiation. The correspondent was apparently using the latter type. About 94 per cent of this lamp's radiation of wavelengths less than and including 313 millimicrons is contained in the resonance emission line at 254 millimicrons.

Only visible rays, i. e., rays between 760 and 380 millimicrons, are capable of penetrating the crystalline lens, producing physiologic photochemical changes in certain cells of the retina.

Rays from 380 to 295 millimicrons are absorbed by the lens and cause it to fluoresce, which seems to act as a protection to the retina. If an eye in which the lens has been enucleated is irradiated with these rays, certain changes occur in the cells of the retina at once or in several hours, but they return to normal in a few days.

Radiation of a wavelength less than 295 millimicrons is absorbed by the cornea and conjunctiva.

The lamp mentioned by the correspondent gives 94 per cent of its radiation at the line of 254 millimicrons. This radiation, at the distance of 24 inches for one minute, could cause a conjunctivitis and a cloudiness of the cornea. There should have been an interval of a few hours before this occurred. These conditions disappear in a few days, and with this dose of ultraviolet radiation, no permanent injury should occur.

SALE OF SPECTACLES AT CHEAP RATES

To the Editor—Here is a newspaper clipping from a Cleveland news paper. According to this ad a person can get his eyes examined for which I get from \$5 to \$10 together with a pair of glasses for \$4.50. This is less than the wholesale price of the same glasses from the American Optical Company. Can you kindly tell me where they get these glasses? Are they any good? I am informed that one company in Cleveland does a \$60,000 optical business a year. Certainly this cannot all be humbug. Another company in Akron does a \$20,000 optical business a year. The result is that my refraction business is chimerical. Is it possible to buy glasses cheaper than those obtainable from the American Optical Company etc.? It seems to me that something ought to be done, and I ask your cooperation in this matter.

FRED V GAMMAGE, M D, Akron Ohio

ANSWER—Optical merchandising principles do not vary materially from the principles of merchandising of other goods, and in the optical trade there are first, second, third and ad infinitum qualities of goods exactly as there are in the cloak and suit business. A suit may be purchased from \$10 to \$100, depending on the quality of the material and the character of workmanship employed in production. Optical goods have a similar range in price affected by the same factors, but unfortunately the public cannot differentiate between first quality and shoddy optical goods. Therefore the cut-rate optical houses, the chain store opticians, the blatant "low-price" houses, the optical

Book Notices

How to Budget Health Guilds for Doctors and Patients By Evans Clark, Director Twentieth Century Fund, Inc. Published for the Twentieth Century Fund, Inc. Cloth. Price, \$4 Pp 328, with 11 illustrations New York & London Harper & Brothers, 1933

The reader of this book can scarcely fail to be impressed with the idea that the purpose of the book, coming as it did so closely on the heels of the Report of the Committee on the Costs of Medical Care, is to bolster the views expressed in the majority report of that committee. Although the report mentioned is referred to frequently, nothing is said about the fact that the views contained in the majority report were not unanimously concurred in, actually, of course, there were two minority reports, one of them signed by a considerable number of the physicians on the committee who are engaged in treating the sick, and two dissenting opinions by laymen who would not sign the majority report.

The author of this book is the director of the Twentieth Century Fund, Inc., the founder of which, Edward A. Filene, was greatly interested in developing the committee, as stated in an editorial in *THE JOURNAL*. Although this interest and initial stimulus has been denied by some members of the executive board of the committee, the following statement is found in Mr. Clark's preface:

The Twentieth Century Fund has for some years been interested in the solution of this problem. Its president, Edward A. Filene, was active in the formation of the Committee on the Costs of Medical Care which has now completed a five year program of research designed to obtain the essential facts of the situation and to suggest constructive measures for the mitigation of existing evils. The Twentieth Century Fund assisted in underwriting the organization of the Committee in 1927 and the formulation of its program. It also made annual contributions toward its work.

How to budget health is described in chapter 1, as the medical guild plan. The material in chapter 1 has been taken largely from an article by the director of the fund which appeared in the *Atlantic Monthly* in October, 1930, entitled "A Cure for Doctors' Bills."

A medical guild may be defined as "an institution which combines all of the following elements: (1) an all-around medical service, including hospitalization, without any drastic limitations and exceptions, through a well balanced group of doctors, (2) a fixed annual fee covering such service, and (3) periodic health examinations," this service to be given to all members or subscribers of the guild. Medical guild seems to be but another term for group practice or hospital medical center, as proposed in the majority report of the Committee on the Costs of Medical Care. The guild plan, however, is elaborated on much more extensively and contains features not brought out in the report. It is a utopian scheme designed to relieve the medical profession, or at least those members who constitute the guilds, of which there may be many, of their worries and cares by creating for them a larger and more stabilized net income, and for the members or subscribers of the guild the highest type of complete medical service at a lower operating cost, for a fixed fee.

In the succeeding chapters an attempt is made to convince one how these two commendable but somewhat contradictory ends may be accomplished. A group of well established doctors of the highest medical attainments are to organize and incorporate as a guild.

The next question is how to secure members or subscribers. It is supposed that each doctor in the group as soon as the formation of the guild has been publicly announced would bring all of his families and patients into the guild as subscribers. This would start the guild right with several hundred or possibly thousand subscribers, depending on the number and standing of the medical men comprising the guild. Other persons would become attracted to the plan (so it is thought) by favorable friendly newspaper articles and "by personal solicitation by the word of mouth of satisfied patrons." "Even a new and independent guild organization would of necessity be automatically self recruiting."

The problem of "selling" the guild to the public is obviously of primary importance. It must "not violate the ethics of the profession as interpreted by those who control its destinies in the locality where the guild is established." The methods

used to recruit members are by paid advertisements, by direct mail promotion and by personal solicitation—methods that are contrary to recognized ethical ideas.

"Any estimate of the fee to be charged by the medical guild depends necessarily on two factors:

"*The size of the guild* The cost must be guessed in advance in order to show how much income must be obtained per year to cover the expenses of operation.

"*The number of subscribers* The fee charged to each subscriber would vary directly with the number called upon to divide the costs." The cost of adequate medical care is placed at \$42.55 per person, which sum "may be taken as a rough estimate of the fee which medical guilds would have to charge. It must be carefully noted, however, that this is an *average* figure. The costs in large centers like New York and Chicago would be greater than smaller towns and consequently guild fees would have to be higher. It is probable, however, that guild service could be given even in the largest cities for from \$50 to \$60 per year per person."

It is frankly admitted that, if the older men with well established practices could not be induced to give up their private work and join a guild, younger men, recent interns or assistants might be secured for the salaries paid.

At one place it is stated that these guilds would be successful financially and be able to pay the physicians larger salaries than they had earned in private practice. At another it is claimed that for the first few years they would not be able to meet expenses and that it would be necessary to have some kind of philanthropist subsidize the guilds in order that they may be able to pay the running expenses. Another solution of this phase of the question which is proposed by the author is that the state by general taxation pay the subscription fee for all those who are unable to pay it themselves. This is but another way of proposing compulsory health insurance under government supervision.

In discussing the guild plan, Mr. Clark says that it was found to be illegal in New York State, where it was suggested that it might be tried, as "the general rule that a corporation cannot practice medicine is well established in New York." It is also pointed out that the scheme would probably come under the laws governing insurance agencies. However, the author naively remarks that there may be some way found to beat the law.

The book makes an evening's interesting reading, but the scheme proposed is so replete with uncertainties and objectionable features that it cannot be said to offer much of value in solving the question of medical care for the people.

Précis clinique et opératoire de chirurgie infantile Par L. Ombredanne, professeur de clinique chirurgicale infantile à la Faculté de médecine de Paris. Third edition. Cloth. Price, 140 francs. Pp 1479, with 1008 illustrations. Paris: Masson & Cie 1932.

The first edition of Ombredanne's monograph on clinical and operative pediatric surgery appeared in 1923. The book is one of a set known as the Collection de précis médicaux, consisting of short works or compendiums especially for students and physicians who desire a concise volume. Although prepared in a handy size and as a compendium, this edition covers so many pages that, in combination with comparatively small type, it is in reality a textbook. It is well illustrated. The material is divided into two parts. The first part, covering about 250 pages, deals with general pathology. After a short discussion concerning the question of anesthesia, preparation for operation, hemostasis and postoperative complications, this section ends with a discussion of rapid death occurring postoperatively with pallor and hyperthermia, a condition that occurs most frequently in infants between the ages of 6 days and 6 months, less often during the last six months of the first year, and later, being progressively rarer as the age increases. Without claiming to know the cause, the author says that it is not due to dehydration, bronchopneumonia, hemorrhage, shock or swallowed blood and that there is no proof that it is caused by hepatic insufficiency, acute hydrocephalus, anaphylactic shock or traumatic shock, though these all are spoken of hypothetically. Prophylactic measures advocated are continuance of the usual regimen, avoidance of purging, the use of general anesthesia, rapid performance of operations, and certain postoperative measures. If the condition has developed, he recommends cold baths, beginning at room

VOLUME 100
NUMBER 13

temperature and gradually being made colder. The bath lasts two hours, and, after an intermission of two hours, if it is still indicated, it is repeated. In addition, he gives epinephrine by mouth, 3 drops at a time, with the feedings, up to a total of from 20 to 30 drops. The other topics discussed in the first part include traumatism, dystrophies of bones, infections of bones and joints, and tumors. The second portion of the volume, of about 1,200 pages, consists of regional presentation of the pathologic conditions and surgery of infancy. The congenital malformations of each region are discussed first, and then the acquired lesions and diseases. Etiology, pathology, symptoms, diagnosis and treatment are fully presented. Indications for and descriptions of operations are given in detail. Only those procedures are described which the author has found to be of value and can personally recommend. The material has been brought down to date, is surprisingly full for a volume for students and, indeed, is of interest and value for any surgeon who is able to read French.

Diseases of the Mouth. By Sterling V. Mead, DDS, M.S., B.S., Professor of Oral Surgery and Diseases of the Mouth, Georgetown University Dental School. Fourth edition. Cloth. Price \$10. Pp. 932, with 563 illustrations. St. Louis: C. V. Mosby Company, 1932.

This book attempts to cover in a comprehensive manner the whole field of pathology, diagnosis and treatment of all diseases of the mouth. The author states in the introduction, "This volume has been written primarily as a textbook for dental and medical students." Since neither the physician nor the dentist is likely to be favorably impressed by the manner in which his particular field is covered, one may question the attainment of the purpose quoted. The pathologist is faced by not less than sixty photomicrographs either without significance or unsuited for the purposes of teaching and illustration. The material on laboratory technic is covered much more adequately in the special textbooks on laboratory diagnosis. Such subject matter as that on dental caries (chapter vi) must prejudice the dentist against the book as a whole. The clinical surgeon must lose faith in an author who proposes in the chapter on osteomyelitis (p. 640) that "at least 30 ounces of orange juice should be taken daily." On the other hand, there are features of the book that are highly commendable, which, in spite of the defects just mentioned, will recommend it to many for use either as a textbook or as a reference book. The text is complemented by numerous accurate reproductions of roentgenograms covering a wide range of conditions, the subject matter on diagnosis, testing tooth vitality and use of transillumination is well worth reading and careful study, and each chapter is followed by a comprehensive bibliography.

Der Abtissin Hildegard von Bingen Ursachen und Behandlung der Krankheiten (causae et curae). Uebersetzt von Professor Dr. Hugo Schulz. Paper. Price 10.80 marks. Pp. 235. Munich: Verlag der Aerztlichen Rundschau Otto Gmelin, 1933.

The author, who combines linguistic scholarship with an intuitive understanding of the spirit of the twelfth century, deserves thanks for making it easy to study one of the earliest documents of German monastic medicine. It is a strange mixture of the teachings of Galen, revived at the school of Salerno, and of the teachings of the Bible. Intermingled with the theological theories are the keen personal observations of the nun, her quite modern conceptions of the constitutional fundamentals of human disease, and an insight into the insufficiency of the pharmaceuticals of her time. "These prescriptions have been given by God himself, and they will either cure man or he has to die, or God does not desire that he shall be cured from his disease."

A New Physiology of Sensation Based on a Study of Cardiac Action. By W. Burridge, D.M., M.A., Professor of Physiology, Lucknow University. Cloth. Price \$1.50. Pp. 70. New York & London: Oxford University Press, 1932.

Although this small volume may contain a record-breaking philosophical discussion of a physiologic process, namely, sensation, it seems rather to be a word or sentence salad. A newly coined jargon used in well rounded sentences gives the reader no inkling of what the author has in mind in spite of the sixty-seven pages of text. No practitioner of medicine will care to read the book.

Economic Mammalogy. By Junius Henderson, Curator of University of Colorado Museum and Elberta L. Craig, Museum Assistant. Cloth. Price, \$1.60. Pp. 397. Springfield, Illinois: Charles C. Thomas, 1932.

The authors have attempted to bring together from widely scattered sources as much information as possible concerning the economic relations of mammals both to one another and to man. It has been impossible to include the entire 12,540 species and varieties of mammals known to exist on earth, but most of those in North America as well as many in other parts of the world are discussed. The book is divided into two parts. Part I deals with a general discussion on such topics as mammals as a source of food, their relation to the industries such as the fur and leather trades, and their esthetic relations to man, as pets and as game, and so on. In the two short chapters on diseases of animals and their parasites, it is disappointing to note that, while a whole page is given over to the discussion of tularemia, the much more economically important disease of bovine tuberculosis is dismissed with one sentence quoting statistics eighteen years old. Part II is devoted to a systematic discussion of various orders and families, from the primitive egg laying mammals of Australasia to the primates up to but not including man. This furnishes a quick reference, giving the salient facts concerning the economic importance of the various mammals. The book is written in a readable language which does not require an extended knowledge of zoology to understand. There are copious footnotes and references on almost every page, which form the chief recommendation for the publication.

Medicolegal

Practice of Dentistry by a Corporation

(*Parker v. Board of Dental Examiners of State of California* (Calif.) 14 P. (2d) 67)

A corporation, operating under the corporate name "Painless Parker Dentist," was organized under the laws of California to conduct, own, operate and control dental offices. It appointed one of its incorporators, Painless Parker by name, a licensed dentist, as its manager and chief surgeon. The corporation, in conjunction with another, the Associated Dental Supply Company, operated a chain of dental offices. Parker employed a licensed dentist to manage each office, and each such manager employed licensed dentists to perform necessary dental operations in the office in his charge. Parker, however, maintained the management and supervision of the entire business. The California board of dental examiners deemed Parker's conduct unprofessional and suspended for five years his license to practice dentistry. The district court of appeal, first district, division 2, California, set aside the order of the board (*Parker v. Board of Dental Examiners*, 1 Pac. (2d) 501, *THE JOURNAL* 98 2311 [June 25] 1932). The board thereupon appealed to the Supreme Court of California.

The board contended that conducting, owning, operating and controlling dental offices constituted the practice of dentistry within the purview of section 11 of the dental practice act, that a corporation cannot be licensed to practice dentistry, and that any licensed dentist who aids a corporation in performing any of the acts named above is aiding "an unlicensed person" to practice. Parker claimed, however, that the term "unlicensed person," as used in the prohibition of "aiding and abetting any unlicensed person to practice dentistry unlawfully," refers only to natural persons, who might be licensed under the act, and not to a corporation owning or operating a dental office.

It must be conceded, said the Supreme Court, that the legislature has power to regulate the practice of dentistry. Good moral character and "fitness" to practice dentistry are statutory requirements imposed by the dental practice act. The letter of the act authorizes persons only to engage in the practice of dentistry. The underlying theory on which the whole system of dental laws is framed is that the state's licensees shall possess consciousness, learning, skill, and good moral character, all of which are individual characteristics, and none of which is an attribute of an artificial entity.

Surely the state, for the better regulation of the practice of dentistry and as a means of preventing evasions of the law, and with the object of more readily fixing statutory responsibility, has the power to limit such practice to natural persons.

Parker insisted that there is a distinction between the practice of dentistry, which the statute undertakes to regulate, and the purely business side of the practice, and that if the management or conduct of the "business side" by a layman is inhibited by statute, then the statute is to that extent unconstitutional. But, said the Supreme Court, the law does not assume to divide the practice of dentistry into departments of that kind. The subject is treated as a whole and must be so treated necessarily. If Parker's contention is sound then the proprietor of the business may be guilty of gross misconduct in its management and violate all standards which a licensed dentist would be required to respect, and stand immune from any regulatory supervision whatsoever. His employee, the licensed dentist, would also be immune from discipline, on the ground that he was but a mere employee and was not responsible for his employer's misconduct. Public policy will not countenance such a condition. If Parker's contention is sound, the dental practice act is impotent to accomplish the purpose it was intended to serve, namely, to promote the safety, health and welfare of the people of the state.

In the opinion of the court, the corporate practice of dentistry tends to relegate the welfare of the patient to the pecuniary interests of the corporation. In this case, the court said, *Painless Parker Dentist*, a corporation, and the *Associated Dental Supply Company*, a corporation, are the employers of *Painless Parker*, the licensed dentist. The corporations, which are purely commercial enterprises and none of whose directors need be licensed dentists, are the masters of the situation and may with or against the wish of *Painless Parker*, the dentist, employ such licensed persons as may be to their commercial advantage, having less regard for the skill or fitness of the persons so employed than would a licensed proprietor who is solemnly charged by the obligation he assumes to the state to respect the salutary provisions of the dental practice act. If *Painless Parker*, the licensed dentist, owed his first allegiance to his employers, the corporations, then he owed but a secondary and divided loyalty to the patient.

The practice of dentistry is not open to commercial exploitation. Such would be its fate if the methods adopted by Parker, the defendant, should become general. That a corporation may not practice law, medicine or dentistry is a settled question in California. These professions, involving a relationship of a personal as well as a professional character, cannot be placed in the same category as pharmacy, architecture or other vocations wherein no such relationship exists.

Parker contended that the long period of time during which he had operated and the interpretation that the board and its legal advisers had placed on the dental practice act during that period in permitting him to operate were entitled to weight in this proceeding. For a period of some fourteen years, said the court, the board and Parker have had frequent controversies as to the legality and professional propriety of the methods he employed in the practice of dentistry. At no time was the subject set at rest. Delayed action, however, on the part of those charged with the execution of a law will not be permitted to annul the law. It may be considered by the court as a reason for mitigating punishment, but the court is not absolutely bound to regard it.

For the reasons stated, the order of the board suspending Parker's license to practice dentistry for five years was affirmed.

Epidemic Meningitis an Accidental Injury—*Arquin*, an intern in the Cook County Hospital, assigned to the contagious ward, contracted epidemic meningitis and died. His widow sought compensation under the Illinois workmen's compensation act. An award by an arbitrator in her favor was set aside by the industrial commission but affirmed by the circuit court, Cook County, and by the Supreme Court of Illinois. An injury, said the Supreme Court, may be occasioned as readily by disease as by a blow. A disease accidentally acquired may be an accidental injury. When *Arquin* contracted epidemic meningitis and died, he died as the result of an accidental injury arising out of and in the course of his employment as an intern in the Cook County Hospital.—*Arquin v Industrial Commission (Ill)*, 181 N E 613

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below

American Heart Journal, St Louis

8 155 296 (Dec.) 1932

- Amplifier for Heart Sounds Operating on Alternating Current. F D Johnston and L I Barbier Ann Arbor Mich—p* 275

Paroxysmal Tachycardia of Ventricular Origin—Wilson and his associates report four cases of paroxysmal tachycardia and review the eighteen cases reported in the literature. They conclude that there is a type of paroxysmal ventricular tachycardia in which the abnormal mechanism is induced by emotion and exertion. The attacks may be long, but more often short attacks separated by periods of extrasystolic arrhythmia occur in rapid succession. In the majority of the cases there is no other evidence of cardiac disease. Patients with this disorder are usually seriously incapacitated. Small doses of quinidine are often beneficial but do not always prevent the occurrence of attacks. In one of the cases studied by the authors a long paroxysm of ventricular tachycardia was frequently interrupted temporarily by short attacks of paroxysmal auricular tachycardia.

Dilatation of Left Auricle—Nichols and Ostrum present five cases showing unusual dilatation of the left auricle. Esophageal obstruction was produced in two and was so pronounced in one as to lead to gastrostomy. In three of the patients the left auricle extended far to the right and formed a portion of the right cardiac border. Early in the disease roentgen examination is essential for the correct diagnosis, but in later stages diagnosis may be suspected clinically from fairly suggestive physical signs. The symptoms, physical signs, pathologic changes and vascular dynamics of this condition are reviewed. It is practically always seen in rheumatic hearts with mitral stenosis and auricular fibrillation. The exercise tolerance and lack of congestive failure in some patients is remarkable.

Spontaneous Rupture of Aorta—Arenberg gives a detailed report of a case of spontaneous rupture of the aorta into the pericardium in which careful histologic examination failed to reveal contributory pathologic changes. Instances of such spontaneous rupture are not rare, but the condition is

practically never recognized during life. A review of the literature shows that such ruptures occur twice as frequently in males as in females, age seems not to be an important factor, in many instances no changes have been found in the aortic wall, and most of such tears take place in the ascending aorta and are transverse. At first usually the rupture involves only the intima and the media, the latter is then separated from the adventitia by a dissecting hematoma, which ultimately ruptures through the adventitia at some distance from the point of the primary tear. Frequently the external rupture takes place into the pericardial sac.

Effect of Celiac Ganglionectomy on Sugar Tolerance—De Takats and Cuthbert studied the effect of celiac ganglionectomy on the sugar tolerance of normal dogs. They observed that the intravenous sugar tolerance of normal dogs does not vary spontaneously under basal conditions. The removal of the celiac ganglion results in a decided, persistent rise in tolerance in every instance. Dextrose administered intravenously disappears more rapidly from the blood stream than before the operation. The dogs become more susceptible to insulin. Denervation of the liver does not have a similar action. These data show that the celiac ganglion mediates nerve impulses, the exclusion of which brings about either an increased insulin production or a reduction in the insulin requirement.

Effect of Galactose on Human Respiratory Exchange—Carpenter and Lee determined the effects of the ingestion of from 5 to 40 Gm of galactose on the respiratory quotient and the total metabolism in a human subject by means of an open

circuit respiration apparatus and a helmet. The base line for the day was measured in from three to four fifteen-minute periods, and ten fifteen-minute periods were run after the sugar was taken. The subject had a low tolerance for this sugar, as the total reducing substances in the urine for approximately three hours varied from 0.7 Gm after the ingestion of 5 Gm to 3.1 Gm after the ingestion of 40 Gm of galactose. All amounts of galactose caused a rise in the respiratory quotient, the maximum rise in a period varying from 0.04 with 5 Gm to 0.17 with 40 Gm. This sugar somewhat resembles fructose in its effects on the quotient, although it differs from both fructose and dextrose in that there was a fall to below the preingestion level during the latter part of the two and one-half hours after ingestion. The rise in apparent carbohydrate combustion varied from 1.1 to 1.28 Gm, which represented from 13 to 32 per cent of the amount ingested. The maximum increase in heat production over the base line level in a fifteen minute period varied from 10 per cent with 10 Gm to 18 per cent with 40 Gm. The summation of increases in heat production in successive periods varied from 0.6 calory with 5 Gm to 12.6 calories with 40 Gm and the specific dynamic action varied from 3 to 8 per cent. Galactose resembles fructose in its effects on the respiratory quotient and carbohydrate combustion and resembles dextrose in its effects on the heat production.

Cortical Suprarenal Extract and Blood Cells—Corey and Britton state that suprarenalectomy produces marked numerical changes in the cellular elements of the blood. With the development of symptoms of suprarenal insufficiency, the erythrocytes commonly increase from 50 to 100 per cent, this change is probably due to fluid loss from the blood. The total leukocyte counts are meanwhile found to be decreased to a similar extent. There are pronounced reductions in the neutrophil counts, sometimes almost to the disappearing point. The lymphocytes show a concomitant increase in percentage. The administration of cortical suprarenal extract to animals suffering from severe suprarenal insufficiency and showing profound blood cellular disorganization resulted in complete restitution of the normal cell values. Recovery of the blood cell elements to normal values was coincident with general improvement in the condition of the animal. Control experiments with epinephrine, dextrose and saline solutions were negative, with the exception of the partly effective action of epinephrine on the white rat. There were no noteworthy leukocytic changes in the splenectomized controls. Splenectomysuprarenalectomized animals showed responses after operation and after extract treatment, however, which were similar to those mentioned. The authors consider the possibility that the neutrophilopenia of suprarenal insufficiency is related to the clinical condition of "agranulocytosis."

Squamous Cell Carcinoma of Skin—Martin states that the number of cures of squamous cell carcinoma of the skin produced by efficient irradiation equal those produced by surgery

and that the cosmetic results are much better. The pessimistic attitude that exists among dermatologists is apparently due to extreme conservatism and inadequate dosage. Surgical methods are valuable adjuncts in treating tumors growing on cartilage and in neck dissections when only one or two malignant glands are present. It is the author's custom to treat all primary squamous cell skin lesions with roentgen radiation alone unless marked induration is felt beneath the tumor or the process extends well out onto a mucous membrane as, for instance, at the corner of the mouth. In such cases the treatment is supplemented with radium. Before primary lesions are treated, they are surrounded by a lead foil shield which allows a border of normal tissue about one-eighth inch wide to be exposed. A cone attached to the under side of a tube stand is then brought down so that it exerts firm pressure on the lead shield and covers the diseased area. The factors used are an 87 kilovolt 5 milliamper peak, a target skin distance of 10 inches, a filter of 0.5 mm of aluminum and exposures of five minutes. With a Victoreen ionization apparatus placed so as to take back-scattering into account, this dose amounts to 555 roentgens with an aperture of three-fourths inch in diameter, 640 roentgens with an aperture of 1½ inches, and 666 roentgens with an aperture of 2 inches.

Roentgen Treatment over Vegetative Nerve Centers

—Langer reviews the literature and states that the effect of roentgen radiation on the vegetative nervous system was proved in animal experiments with a special technic by him in 1923 and that his observations have been corroborated by others. He explains the effect of roentgen radiation on the vegetative nervous system in a form of two stages: (1) irritating, (2) quieting effect. He reports three cases of different diseases of the skin illustrating these effects. He attempts to persuade radiologists to study and cooperate with his observations. He advocates the desirability of trying roentgen treatment before surgical removal of sympathetic ganglions or trunk resection. The technic presented might prove of value as a diagnostic test as well as a help in clinical research and does not seem to show any permanent injurious effect on the patient. It consists of the application of roentgen radiation either directly to the autonomic nerve center in the diencephalon or to other autonomic centers. All the cases have been treated with short wave therapy of from 185 to 200 kilovolts, 0.5 mm of copper, 3 mm of aluminum, 35 cm skin target distance, wavelength 0.166 angstrom, and 4 milliamperes.

Injection of Iodized Poppy-Seed Oil into Knee Joint

—Burman and his associates injected iodized poppy-seed oil into the knee joints of thirteen patients. The age of the patients, six men and seven women, varied from 34 to 61. Twelve of the thirteen suffered from mild to severe arthritis of the knee over a period ranging from two months to three years. The thirteenth patient, a man, presented a bursitis under the insertion of the biceps femoris tendon and was used as a normal control joint. Only two cases showed marked bone changes roentgenographically, marked narrowing of the interarticular space with irregularity, indicating definite bony and cartilaginous destruction. In one case a sterile effusion of the knee was tapped, 40 cc of a light brown fluid, with some fibrin in it, being obtained. Most patients complained of pain in and about the knee joint, swelling of moderate degree, and crepitation on motion. Motion was usually almost normal. In three cases, extension was slightly limited to 170 degrees and flexion was definitely lessened, even up to 90 degrees. Practically all cases showed enlargement of the infrapatellar fat pad and hypertrophy of the synovial membrane. In one case a foreign body was seen in the roentgenogram with definite limitation of motion. About three hours after the injection, all the patients were seized with severe, stabbing pains in the knee joint, radiating up the thigh and down the leg. Sleep was impossible. The acute pain lasted for about twelve hours and then gradually abated, in a duller, gradually lessening form, the pain persisted from two to eleven days. With the pain, the signs of a chemical synovitis of varying degree were noted—swelling of the joint, local heat, diffuse tenderness and refusal to move the joint because of pain and stiffness. No redness was present. The chemical synovitis, apart from the severity of the pain, lasted from one to two weeks. The authors conclude that the intra-articular injection of iodized poppy-seed oil is a dangerous procedure and that it should never be used.

Value of Program for Collapse Therapy—Head and his associates believe that phrenicectomy is of definite value as an independent procedure in the treatment of pulmonary tuberculosis. Its use as a primary procedure decreases the number of cases in which artificial pneumothorax is indicated. It discourages the development of extrapulmonary complications. Spread to the opposite lung, or a lighting up of arrested or quiescent processes there, is less likely to occur if the operation is performed. Active disease in the opposite lung is more likely to clear up. Phrenicectomy discourages the development of pleural adhesions and so does not interfere with the later induction of artificial pneumothorax if this should become necessary. It does not prevent collapse therapy of the opposite lung. In general, the percentage of favorable results is in proportion to the extent of involvement, the size of the cavities and the tendency to fibrosis and retraction of the lesion, but phrenicectomy frequently fails to effect cures in apparently favorable cases and often effects them in soft extensive lesions with large cavities and an absence of fibrosis. The authors wish to state that this program has been applied as an experiment and by no means expresses their conception of the proper treatment of tuberculosis. They feel that each tuberculous patient should be treated individually. Collapse therapy should be applied earlier and more frequently than it has been heretofore.

Value and Limitations of Phrenicectomy in Advanced Tuberculosis—Bronfin and Chernyk give a tabulated report of the clinical results of phrenicectomy performed on 183 patients from 1924 to September, 1931. The extent of the pulmonary involvement or complication in each individual patient for which this operation was deemed advisable is indicated by group classification. From a study of the results they conclude that phrenicectomy is chiefly applicable in the treatment of predominantly unilateral lesions with little or no cavitation when pneumothorax is impossible and a routine sanatorium regimen is not productive of beneficial results. It has a wide field of usefulness in bilateral cases which have a limited contralateral lesion without definite cavitation. In from 40 to 50 per cent the palliative effect, decrease in cough and sputum and greater ease of expectoration, is quite marked. It may be an important aid in checking hemoptysis. It frequently converts an unsatisfactory pneumothorax into an effective collapse. It exerts a favorable influence on those complications so frequently resulting from pneumothorax, notably empyema either with or without bronchial fistula. Its usefulness in chronic lesions with bilateral cavitation, associated emphysema and general debility, even when there is a major disease on one side with recent lower lobe involvement is extremely limited and it is generally contraindicated.

Superiority of Liquid Petrolatum over Olive Oil in Oleothorax—Since Bernou made his first report on oleothorax in 1922 this method of therapy has been quickly adopted in tuberculosis clinics throughout the world. In the application

of oleothorax in their clinic, Goldenberg and Flanchuk observed through experimental work the action of olive oil and liquid petrolatum, without the addition of any disinfecting substances, on the healthy pleura of rabbits. Olive oil, as well as petrolatum, after being introduced into the pleural cavity produces an inflammatory reaction. This reaction is more marked when olive oil is used. Olive oil, even after being in the pleural cavity of a rabbit for a short time, undergoes marked physicochemical changes, whereas petrolatum undergoes changes only after a longer presence in the pleural cavity. The changes that take place in olive oil, and particularly petrolatum, while in the pleural cavity, and their general influence on the organism, warrant further detailed study. According to the data obtained by their experiments, the use of liquid petrolatum is preferable to olive oil in the field of oleothorax. The entire question requires further observation in the clinic, during which the differences noted in the reactions of the pleura of the human being against those of the experimental animal should be borne in mind.

Cottonseed Oil in Pneumothorax—Bethune reports the case histories of three tuberculous patients in whom pure cottonseed oil appeared to be a useful substitute for air in progressively obliterative pneumothorax. The oil in these cases has been tolerated without local or constitutional reaction. The oil should not be used as a substitute for an ordinary pneumothorax, nor should it be placed on the diaphragm but only on the shelf formed by the adherent base of the lung. The rate of absorption of the oil will vary from 0.05 to 0.5 cc a day. The author suggests that the use of the oil be restricted to semi-permanent collapse and that it be drained after two or three years, as no case can be considered safe in which any foreign material—air, fluid or solid—is interposed between the two pleural surfaces. His technic of injection is as follows. The patient lies flat on his back. A 16 gage and an 18 gage needle are put into the pneumothorax cavity in the second interspace side by side. The pneumothorax pressures are taken, then the two needles are left open to the air. The sterile cottonseed oil is heated to body temperature in a water bath and injected with a 50 cc. Luer syringe through the 16 gage needle. After each 50 cc injection the pressure of the remaining pneumothorax is taken with the manometer. It should show a zero or slightly negative pressure. The air is allowed to escape through the 18 gage needle as the oil is injected through the other. As soon as no true pressure can be obtained by the water manometer attached to the 18 gage needle, or as soon as oil appears in this needle, no more oil is injected. Both needles are withdrawn and the punctures tightly strapped. Fluoroscopy done immediately afterward will show the oil with a small apical cap of air on top of it. This cap of air will be absorbed in a few days, leaving the oil at a negative pressure. In testing the subsequent oil pressure, the author uses a U tube of 5 or 6 mm internal diameter, filled with cottonseed oil. The scale is marked in true pressures of centimeters of oil, as on a water manometer. Owing to the specific gravity of oil being 0.9, corresponding oil pressures are nine tenths of water manometer pressures. With the patient sitting upright, a 16 gage needle is put in the lowest part of the oil pocket, and the oleomanometer, which is completely filled with oil, is connected with a short rubber tube to the needle and the pressure is read on the open limb.

Scaleniectomy in Treatment of Tuberculosis—Clyne points out that phrenic exeresis should not be depended on alone in apical lung lesions but should be combined with scaleniectomy. Scaleniectomy alone has induced a degree of immobilization in the involved apex in a series of fifty-two cases. Of twenty cases in which a phrenic exeresis had been done from six months to three years previously and improvement had stopped, ten were improved and ten not improved, of twenty-nine cases in which the combined operation was done, improvement was noted in nineteen with no improvement in ten, of three cases in which scaleniectomy was done alone because of apical involvement with complicating asthma, and because it was thought best not to embarrass respiration by paralyzing the diaphragm, two were improved definitely. Scaleniectomy is indicated in pneumothorax cases with apical activity, when the upper lung has not been collapsed. Scaleniectomy and phrenic exeresis should in most cases precede a paravertebral thoracoplasty, because the first rib is released to allow greater caudal pull or the intercostal muscles, especially in front.

Dermatologic Conditions of Fetus—Lynch outlines the cutaneous diseases present at birth. He believes they are due to conditions related to fetal environment, ectodermal anomalies, keratoses, keratolyses, disturbances of subcutaneous tissue, nevus, new growths or infectious diseases. He reports a case of generalized eruption in a six months fetus born twenty-seven days after vaccination of the mother. The eruption consisted of umbilicated pustules and flaccid bullae. Similar cases have been described in the past as intra-uterine variola. An accurate diagnosis could have been established only by inoculation experiments with the fluid of the lesions. The history, appearance and pathologic studies were not sufficient to distinguish between these two possibilities. The author believes his case to be one of pemphigoid vaccinia occurring in the fetus.

Bowen's Precancerous Dermatitis—Anderson reports a case of Bowen's disease presenting a history of arsenical medication, the presence of arsenic in the tissues and urine, the suggestive simultaneous occurrence of lesions that were clinically multiple benign superficial epithelioma, the presence of a cutaneous horn, the hyperkeratotic lesions on the legs, and the palmar and plantar arsenical keratoses. The author believes that one, and only one, etiologic agent can be responsible for such observations, namely, arsenic. He also reports two cases of benign superficial epithelioma, one multiple and the other single, both accompanied by arsenical keratoses of the palms and soles, in one of which arsenic was demonstrated in the lesion. He discusses the probable relationship of Bowen's disease to multiple benign epithelioma and suggests that arsenic is the etiologic agent in both conditions.

Nirvanol Eruptions—Madden points out that nirvanol, a new preparation used in the treatment of chorea, after it has been administered for a definite time in exact amounts, uniformly produces an eruption accompanied by a definite symptom complex. In chorea, successful results are attributed to the specific reaction that occurs after several days of oral administration. Most observers believe that the reaction is similar to that of serum sickness, but the exact mechanism is not known. Symptoms following ingestion of nirvanol appear with clocklike precision. They are not constant but are more consistent than is the case with most eruptions due to drugs. The histopathologic condition is the same as that found in any toxic erythema. The differential diagnosis rests between the acute contagious exanthems, measles and scarlet fever, and eruptions produced by this drug. There are fairly uniform changes in the blood in all cases. The prognosis of nirvanol sickness is good. Complications are few and usually are of no great consequence. The literature contains only a few examples of severe complications that resulted in sepsis or death.

Action of Pine Oil on Some Fungi of Skin—On the basis of their tests, the Smyths state that pine oil has definite

value as a fungicide against organisms causing such diseases of the skin as ringworm. Considering cost and effectiveness, "very pale yellow" pine oil seems to be the most practical of the materials tested, although it is not the best material for every organism tested. One advantage of pine oil over other possible materials for the treatment of ringworm lies in its low vapor pressure. It stays in contact with the infection for a long time. Two or three applications daily are adequate to maintain almost constant contact, even without poulticing. This is by no means true of all materials now on the market for the treatment of ringworm. For treatment of fungal infections in which the organism burrows under the top layers of the skin, this long continued contact with chance for penetration is a decided advantage. The odor of pine oil is pleasant and it does not stain or otherwise injure clothing, so that its use is not objectionable.

Cerebral Circulation—Finesinger describes experiments in which he demonstrated that during amytal anesthesia the intravenous administration of caffeine sodiobenzoate to cats caused a dilatation of the pial artery, a rise in cerebrospinal fluid pressure and an abrupt drop in blood pressure with immediate return to normal. Local administration of caffeine solution to the pia caused a dilatation of the pial artery and in most cases no change in cerebrospinal fluid pressure or blood pressure. During ether anesthesia the intravenous administration of caffeine caused a constriction of the pial artery from its initial diameter, a drop in cerebrospinal fluid pressure and an abrupt drop in blood pressure with return to normal. After local administration, during ether anesthesia, caffeine had no effect on the pial artery and in most cases caused no change in the cerebrospinal fluid pressure and blood pressure. After recovery from ether anesthesia, when the superficial reflexes were present, the intravenous administration of caffeine caused an acute constriction of the pial artery followed in most cases by an immediate dilatation. In most cases the cerebrospinal fluid pressure dropped and then rose immediately. The blood pressure dropped abruptly and then immediately rose to its normal level, and in most cases exceeded its preliminary level. During amytal anesthesia and after recovery from ether anesthesia there was evidence of dilatation of the measurable arteries, arterioles and venules. Changes in velocity and color were observed, which indicate that the caffeine caused a dilatation of the capillaries as well. The results presented by the author are in keeping with the results of most investigators studying the vascular response to caffeine in other parts of the body. This would suggest that the vessels of the pia respond to caffeine in the same way as do the vessels elsewhere in the body.

Myasthenia Gravis and Exophthalmic Goiter—Cohen and King report a case of exophthalmic goiter with myasthenia gravis. They also review the heretofore reported cases of exophthalmic goiter with myasthenia gravis. The cases of the combination of myasthenia gravis with exophthalmic goiter do not exhibit lesions of the brain or of the spinal cord. There is a similarity in the pathology, pathogenesis and endocrine dysfunction in exophthalmic goiter and myasthenia gravis. The authors call attention to the beneficial effect of ephedrine sulphate in myasthenia gravis alone, as well as when it is complicated by exophthalmic goiter.

Experimental Hepatic Damage —Eisele and Crandall studied the hemato-encephalic barrier in thirty-seven normal dogs, eight dogs with Eck fistulas and two with complete obstructive jaundice. The methods used were the appearance of dyes in the cerebrospinal fluid, Walter's bromide method and the inorganic phosphorus of the fluid. No evidence of a change in barrier function in the presence of liver damage was found. The permeability quotient for bromide is higher and more variable in normal dogs than in normal men. Varying the duration of bromide feeding from two to ten days did not have any apparent effect on the quotient.

Electrocardiograph in Differential Diagnosis of Heart Disease—Cooley points out that a normal electrocardiogram does not necessarily mean a normal heart. Myocardial involvement may be interpreted as myocardial damage only in conjunction with the clinical picture. The amount of myocardial involvement may not correspond to what is seen in the electrocardiogram. One cannot determine whether the involvement is acute or chronic from the electrocardiogram. Physiologic changes can easily be confused with minor changes in the QRS and T waves. Digitalis can produce changes in the QRS and especially in the T wave which can be mistaken for myocardial involvement. It is not possible to make a diagnosis of valvular disease from the electrocardiogram. Like all other mechanical means in medicine, it is only an aid in making the diagnosis. Nevertheless, it is invaluable in many cases. There is a decided practical advantage in differentiating the irregularities of the heart. The prognosis of extrasystoles as a rule is much better than that of auricular fibrillation. Extrasystoles from one focus are less dangerous than those from several foci. Auricular fibrillation is a serious heart condition, while sinus arrhythmia is a physiologic variation. To give digitalis or quinidine to a patient with partial heart block is dangerous, but it is good treatment in auricular fibrillation. The simple tachycardias have a better outlook than the paroxysmal tachycardias. Quinidine is not indicated in the simple tachycardias but it may be in the paroxysmal tachycardias.

The outlook in a sinus bradycardia is obviously much better than in partial or complete heart block. An electrocardiogram may be of value after thyroidectomy in differentiating hyperthyroidism from myxedema. Finally, in the treatment of heart cases the electrocardiogram is essential. It is a valuable aid in digitalization. The appearance of an inverted T wave, extrasystoles or a partial heart block indicates that a digitalis effect is being obtained. The electrocardiogram also serves as a guide in preventing overdosage of such drugs as digitalis and quinidine.

Specific Reaction of Convalescent Serum on Streptococcus Isolated in Poliomyelitis—Rosenow found, by studying the effect of convalescent serum on the streptococcus having characteristic cataphoretic velocity as isolated in cases of poliomyelitis, a marked and specific slowing or charge-reducing effect. This action of the serum increases during recovery from poliomyelitis and is at its maximum during the fourth week after onset of the acute attack, after which there is gradual diminution, but it remains readily demonstrable even twenty years after recovery. The results indicate that the streptococcus isolated by him so consistently in poliomyelitis is not a contamination or postmortem invader.

Rabbit Ovulation Test for Pregnancy—Ware and Main tested 150 patients for suspected pregnancy with the rabbit ovulation test and later established the diagnosis clinically in 100 of these. This test has proved to be accurate with but one possible exception. The number of cases now reported in the literature is over 1000, with an accuracy of over 99 per cent. The authors found the rabbit ovulation test to be of particular

advantage in the diagnosis of hydatidiform mole, missed abortion, ectopic pregnancies, uterine fibroids, the menopause and tubo-ovarian abscesses. The earliest pregnancy giving a positive result was six days after the menstrual period was due. Following delivery, a negative result was obtained in from twenty-four to seventy-two hours.

Sedimentation Rates of Erythrocytes—Vickers and Duryee state that the test for determining the red cell sedimentation rate is easily performed and that the results are easily read. Normal persons have a sedimentation time (Linzmeier method) of over two hours. Severe acute and chronic inflammatory conditions greatly lower this time. The authors employed the test in 348 patients suffering from numerous complaints. They conclude that it is of diagnostic and prognostic value in rheumatic fever, atrophic arthritis and osteoarthritis and in differentiating mild degrees of these conditions from functional disturbances symptomatically similar. The test is also of value in separating inflammatory from noninflammatory conditions of the urinary tract and is of considerable confirmatory evidence in many other conditions.

Intravenous and Subcutaneous Administration of Fluid—Miller and Ponder observed that no harmful results were demonstrated when large quantities of a 0.9 per cent solution of sodium chloride were given, either subcutaneously or intravenously, to normal or pathologic animals. Electrocardiograms did not show any characteristic changes when large quantities of fluids were given intravenously either in normal animals or in those presumably suffering from myocardial damage. Isotonic saline solution, when injected subcutaneously, decreased the amplitude of the R wave in the electrocardiogram. In normal animals, exsanguination and perfusion gave blood volumes that corresponded closely to those given by the dye method. There was an increased concentration of the blood in animals suffering from the effect of diphtheria toxin. The blood volumes, as determined by the dye method, showed no increase after the intravenous injection of large amounts of fluid. This did not agree with the amount indicated by the dilution of the blood, as shown by repeated determinations of the erythrocytes, hemoglobin, serum proteins and plasma increase. No index was found that might be used as a warning against excessive hydration of the tissues. The authors believe that the hematocrit is the most simple test for blood dilution following the administration of fluids postoperatively. Its use would be limited, obviously, to cases not manifesting hemorrhage or evidence of rapid hemolysis.

Barbituric Acid Derivatives—By different methods of comparison, Swanson found that sodium amytal and sodium pentobarbital have practically the same premedication value. Sodium phenobarbital and sodium barbitol possess a comparatively lower hypnotic efficiency. The author emphasizes that the toxicity of these compounds should be accurately determined before any comparisons are made with the methods employed.

Gastric Secretion Caused by Insulin—Boldyreff and Stewart report that both commercial and crystalline preparations of insulin have a definite secretagogue action on gastric glands. The latent period depends on the mode of administration: ten minutes or less for intravenous and about forty minutes for subcutaneous injection. The duration of secretion depends on the dosage, lasting from one to six hours (2 to 8 units of insulin). The stimulating action is monophasic and is not preceded by a period of inhibition of gastric secretion. Small dosages are found to be effective (2 units). Gastric juice secreted in response to insulin has a high acidity, free and total, and high pepsin content. The acidity, determined electrometrically, may attain a pH of 1.0 or even slightly less. It is not improbable that the polypeptide nature of insulin is responsible for its action on the stomach. Gastric secretion caused by this drug, unlike that produced by histamine, is suppressed by the administration of atropine. It is therefore apparent that the secretagogue action of insulin is due to vagus stimulation of the stomach. Intravenous administration of dextrose does not suppress gastric secretion produced by insulin. The beginning of gastric secretion precedes the advent of hypoglycemia. The greatest diminution in the amount of blood sugar occurs a considerable time after the onset of secretion.

Basic Sodium Phosphate as Antidote in Hypercalcemia—Page and Scott describe experiments in which they noted that basic sodium phosphate intravenously injected into normal dogs and dogs in which the calcium has been raised by parathyroid extract lowered the serum calcium. Though by no means ideal, this salt is a fairly effective antidote for hyperparathyroidism.

Hunger Osteomalacia—Eyermann says that during the year 1918 there occurred in Austria and Germany an affliction characterized by pain in the bones which was usually interpreted as rheumatism. The pains were most frequently present in the ribs, back and lower extremities. With progression of the affliction there ensued difficulty in climbing stairs, a characteristic waddling gait and loss of stature. Eventually the sufferers became bedfast, being able to move only with assistance and then with great pain. Deformity as a rule was confined to kyphoscoliosis of the spine, but spontaneous fractures were not infrequent. The bones of the pelvis were seldom involved. The disease occurred chiefly among the poorest classes. The diets of these patients consisted mainly of vegetables and bread with small amounts of flour and sugar. Milk, butter, eggs and meat were unobtainable and a small amount of lard was the only fat. It occurred especially in people past middle age (from 40 to 70) and had nearly an equal distribution between the sexes. There was a greater incidence of cases during the winter. The author reports the case of a man, aged 59, confined to bed for one year because of bone pains, and coinciding in all particulars with the symptom complex of hunger osteomalacia, who recovered completely on a high calcium and phosphorus intake combined with cod liver oil and direct exposure to sunlight.

Respiratory Diseases that Mimic Appendicitis—Lowenstein believes that emphasis should be placed on the tendency of infections of the upper respiratory tract to cause symptoms closely mimicking acute appendicitis, and, while at times there seems to be a causal sequence between inflammation in the

nasopharynx and the appendix, in many instances microscopic study of the latter proves the condition to be merely a lymphoid hyperplasia. The keynote of the whole subject is to place more dependence on the physical signs as evolved from a careful examination of the patient, and less on the variable and often evanescent symptoms.

Carcinoma of Esophagus—Gaetan and Emery present an analysis of sixty-one cases of carcinoma of the esophagus, in all of which the disease was advanced by the time a diagnosis was made. No symptoms were found that could be recognized as early manifestations of the disease, although dysphagia was the first symptom in twenty-five patients and pain in twenty-two. The authors believe that, since these symptoms are not characteristic, one should use both roentgen examination and the esophagoscope if one hopes to make an early diagnosis. In the later stages a typical history of gradually increasing obstruction may develop, but this was present in only 58 per cent of the patients. A typical history is so diagnostic that it is usually safe to make a tentative diagnosis of carcinoma even though it is not confirmed by roentgen examination or the esophagoscope.

Carcinoma of Colon—Babcock states that cancer of the colon, properly handled, gives a better prognosis than cancer of any other part of the gastro-intestinal tract. By eliminating abdominal colostomy, inversion of the rectum, stage operations, and retention of segments of the distal bowel and of the artificial peritoneal diaphragm formed at the brim of the pelvis, he has greatly reduced the dangers of peritoneal infection and intestinal obstruction. In the author's method, the bowel is not entered or sutured until the abdomen has been closed and an occlusive dressing applied to all wounds. In operating he pays attention to the distribution of lymphatics in the rectum and sigmoid as emphasized by Miles. He opens the abdomen through a vertical left rectus incision. After carefully examining the liver, the aortic lymph nodes and the peritoneum for possible metastasis, he divides the left leaf of the mesosigmoid and separates the attached fat and lymphatics from the underlying structures to the midline. On the right side, he divides the peritoneum along the brim of the pelvis, locates and divides the inferior mesenteric or the superior hemorrhoidal vessels between ligatures and, if necessary, ligates and divides one or more of the sigmoid vessels. He then carries the incision along the anterior margin of the pelvis posterior to the bladder, divid-

ing the peritoneum well distant from the diseased intestine and the sigmoid, and separating rectum with fat lymphatics to the floor of the pelvis. This leaves the iliac vessels, ureters and spermatic vessels exposed. He ties a tape of folded iodoform gauze about 2 inches wide and 2 yards long at least 4 inches above the tumor. He carries the ends of the tape back of the rectum to the floor of the pelvis, against which they are firmly packed. The tumor and liberated intestine are laid on the gauze and the abdomen is immediately closed without drainage. He then places the patient in the lithotomy position, closes the rectum by a strong purse string suture, and makes an incision through the pelvic floor in the midline from near the posterior margin of the anus to the left side of the coccyx. Through this incision, the mass of gauze packing is located. He introduces a gauze drain into the pelvis to the right of the withdrawn intestine and, with the protection of a gauze dressing over the perineal wound, cuts the loop of diseased intestine away and ties a large rectal tube into the proximal end. He then introduces a retention catheter and returns the patient to bed. At a later stage, an anastomotic operation to unite the sigmoid to the lower end of the anal ring may be attempted or in some patients the proximal end of the sigmoid may be pulled through the dilated and split anus at the completion of the first stage of the operation. He has also used this operation for diverticulitis to avoid the dangers of an intra-abdominal or stage anastomosis. For comfort the patient should see that the lower intestine is completely emptied every twenty-four or forty-eight hours. He concludes that in about thirty cases this operation gave a mortality of about 10 per cent, which may be reduced to 3 per cent if deaths not directly due to the operation are eliminated.

*Comments on Use of Percaine as Spinal Anesthetic L F Johnson—p 35

Routine Spinal Anesthesia—In using spinal anesthesia, Walters gives morphine hypodermically half an hour before the time of the operation. He places the patient in the left lateral position. He selects the space between the second and third lumbar vertebrae and injects a solution of ephedrine and procaine hydrochloride at the chosen site, infiltrating the path of the needle down to the theca. The ephedrine combats the fall in blood pressure and the procaine renders the actual puncture practically painless. From his observations in 300 cases of routine spinal anesthesia he draws attention to the following points: 1 No serious disadvantage was found in using spinal anesthesia as a routine in the 300 cases. 2 The anesthetic can be repeated without danger. 3 A smaller dose should be given to patients suffering from toxic absorption. 4 In emergency operations on patients not specially prepared, there is less vomiting than after general anesthesia. 5 By the simple method described, a comparatively short duration of anesthesia can be obtained, which makes possible the adoption of the Fowler position soon after the patient is in the ward. 6 The remarkable diminution of postoperative shock after spinal anesthesia has long been recognized, but the well being of the patients, and the air of peace in a surgical ward on "list" days, following the use of this anesthetic as a routine, have yet to be fully appreciated. 7 Spinal anesthesia does not prove an effectual preventive against such postoperative complications as pneumonia and paralytic ileus.

Nupercaine as Spinal Anesthetic—Johnson has administered nupercaine as a spinal anesthetic for the past twelve months, employing the method originated by Jones and described by him. The advantages he claims for it are: (1) the complete degree of anesthesia obtained, (2) the admirable muscular relaxation obtained, (3) the avoidance of primary surgical shock, due presumably to the blocking of afferent impulses at the spinal nerve roots, (4) the slight and transient fall in blood pressure that follows its administration, (5) the absence of untoward after-effects. In his series of sixty patients, only two have suffered from spinal headache. The occurrence of these headaches seems to be minimized by the use of a small bore (11 mm) spinal needle, thereby reducing the liability of subsequent leakage of the cerebrospinal fluid through the hole pierced in the spinal theca. No patient in the series suffered from any form of subsequent paralysis. He concludes that spinal nupercaine appears to be particularly indicated in operations below the diaphragm when some general complication such as lung trouble or diabetes exists, or when the operation may be expected to be lengthy or productive of considerable shock.

Puerperal Sepsis—This being a preliminary report, Mudaliar and Menon do not propose to make any definite statements as to the efficacy of vitamin A therapy in puerperal sepsis. Their experience encourages them in the hope that this type of treatment may be carried on with increasing success. They have observed that the administration of super-D cod liver oil as a prophylactic during pregnancy is exceedingly useful in cases in which a difficult labor may be anticipated. They have given super-D cod liver oil as a prophylactic after labor in cases in which septic complications were likely to arise and it has yielded uniformly good results. The administration of cod liver oil in certain prolonged fevers of the puerperium associated with signs of sepsis has tended to bring down the temperature in a short time. They believe that the morbidity rate and range will be considerably lessened by the use of vitamin A. Of the twenty-five patients in whom this treatment was adopted, and little or nothing else done, their results have been quite satisfactory in twenty-four.

Hexylresorcinol as an Anthelmintic—In their series of cases, Maplestone and Mukerji followed the recommendations of Lamson and his co-workers regarding regulation of diet, and gave doses of 1 Gm of hexylresorcinol in hard gelatin capsules. They treated twenty-one cases of ascariasis with a cure rate of 66⅔ per cent, and an egg reduction, estimated by the original Stoll counting method, of 94 per cent. They treated twenty-six cases of hookworm infestation with 77 per cent of cures, and 71.4 per cent of egg reduction. In the present instance, as on former occasions, they relied on the examination of the stools by Lane's centrifuge method at least ten days after treatment in testing for complete cure, and, while using the egg-counting method as well, they consider their results by Lane's technique the more valuable of the two. In treating ten cases of Taenia saginata infestation they used the same dose and the same method of administration as in the case of roundworm infestation. In no case did they recover the complete worm, but five of the patients reported that they have been free from passing segments for over three months, four have not been cured, and one could not be traced. These results are not nearly as satisfactory as those reported with carbon tetrachloride by Maplestone and Mukerji. It should also be noted that, although the greater part of a tapeworm was usually evacuated a few hours after treatment with hexylresorcinol, the worms were always alive and moved actively when placed in water.

Sulphur Treatment in Mental Diseases—In treating 100 patients suffering from various mental diseases, Dhunibhoy used the technique of sulphur injection originally recommended by Schroeder, viz, injection of the solution suprapariosteally on the lateral side of the femur, preferably between the upper and the middle third. The next best sites are the gluteal regions and the outer sides of the arms when the thighs are contraindicated by any disease condition. From the results he obtained, he states that there can be no doubt that injections of sulphur in olive oil invariably produce a degree of pyrexia, the temperatures ranging from 100.2 F to 105 F and the average being 102.1 F, and that the temperatures cannot be

regulated by the doses. Pain at the site of injection in every case was unavoidable but certainly bearable. Sulphur injections should be given unhesitatingly, because unlike malaria therapy they are perfectly safe and can be given to young and old alike. Earlier cases respond better to treatment than the old chronic cases, and the earlier the treatment is instituted the greater is the chance of recovery. The author concludes that sulphur merits a trial in all early cases of psychoneurosis and psychosis and seems definitely useful in chronic psychotic patients who have heretofore failed to respond to other methods of treatment. It also appears to be useful in cases of benign and secondary stupors. Of his 100 patients, 39 improved and 13 recovered completely.

*Congenital Heart Block. Janet K. Aitken.—p. 1375
*Incidence of Albumin and Sugar in Urine of Normal Women. G. W. Theobald.—p. 1380

Congenital Heart Block—Aitken tabulates the thirty-seven cases of congenital heart block reported in the literature and reports two personally observed cases. The author states that the diagnosis of congenital heart block depends on graphic observations with a history of a slow pulse from an early age, or the absence of a history of any infection that might cause the condition after birth. A large proportion of the cases present other congenital heart abnormalities, the gross pathologic symptoms being associated with these other lesions rather than with the heart block. In three of the reported cases in which there was no other congenital cardiac abnormality the patients were healthy well grown people whose response to exercise was good. The cause of the condition is probably excessive formation of the fibrous tissue which normally develops between the auricle and ventricle, leaving the auriculo-ventricular bundle as the sole muscular connection between the chambers. The excess of fibrous development interferes with the continuity of the bundle. According to Lewis, there are three chief ways in which heart block may be caused: (1) by directly interfering with the conducting tracts, that is to say, the auriculoventricular node, the bundle or both branches of the latter, (2) by stimulating the vagus, or (3) by introducing toxic bodies into the blood stream. In the case of congenital heart block, the second and third causes can probably be put aside. Even if one could imagine vagal stimulation occurring in utero, the effect is usually transient and would not account for the long standing block noted in most of the congenital cases.

Incidence of Albumin and Sugar in Urine of Normal Women—Theobald, in examining the urine of women, found albumin in clinical amounts in 26 of 110 college girls, or 23.6 per cent, 843 of 5,042 postoffice girls, or 16.7 per cent, and 75 of 912 charwomen over 25 years of age, or 8.2 per cent, while only 10 of 22 women medical students consistently passed urine that was either free from albumin or contained less than a trace. In the majority of morning specimens examined not a single cast was seen and on no occasion was more than one granular cast observed. The incidence of albuminuria would not appear to be related to the age of onset of menstruation. Sugar was not detected in clinical amounts in any sample of urine but was frequently found in small amounts in the first urine passed in the morning or in the evening and was least often found in that passed after breakfast or lunch. Twenty-four hour samples of urine are useless for investigating glycosuria or albuminuria, and in the investigation of a case of non-nephritic albuminuria the sample of least value is that passed on arising. Not only is the incidence of albuminuria during the sixth month of pregnancy so low as to demand an explanation, but an existing non-nephritic albuminuria tends to clear up during the early months of pregnancy.

*Treatment of Lichen Planus by Ultraviolet Rays. Elisabeth Skwirsky.—p. 66

Anthrax Simulated by Venomous Stings—Gougerot and Ragu state that the bites of venomous insects may occasionally resemble the cutaneous lesions of anthrax. The anamnesis of a sting, the rapidity of the growth, the soft scab, the ring of vesicles and the painful red edema make it appear identical with anthrax at first, but the absence of general symptoms contradicts this diagnosis and the negative result of bacteriologic examination, the favorable evolution of the disease, without serum therapy or intense local therapy, confirms the diagnosis of venomous insect bite and removes the anxiety of the prognosis of anthrax and the need for a painful, unpleasant treatment.

Lichen Planus—Skwirsky describes the treatment of lichen planus with ultraviolet rays used in the service of Milian. Practically no failures and only exceptional recurrences have been encountered. It is of the utmost importance to give the erythema dose, lesser doses are not only useless but accustom the skin to rays of short wavelength and make it resistant to future applications. Severe painful reactions are rare in persons with lichen planus, and soothing medicaments, which retard cure, are not required, in exceptional cases, simple starch baths may be given. The patient should be carefully examined at each sitting, insolation should not be repeated on a zone still painful from previous insolation. For treatment of generalized lichen planus the body is divided into four irradiation zones, which are irradiated successively every other day with the erythema dose. After these four applications of the erythema dose have been given, the irradiations are applied alternately to the anterior and the posterior surface of the body in periods gradually increased to forty-five minutes. The lamp should be at a distance of 60 cm. The irradiations should be continued till the eruptions have disappeared completely, twelve applications in the average case, and from fifteen to twenty in the resistant case usually suffice. Localized lichen planus is best treated by a lamp for local irradiation in which the rays come through an adjustable orifice which permits regulating the field of irradiation to the desired shape and size. Two irradiations of ten minutes at a distance of 10 cm. are given two days apart. Thereafter irradiations are given every other day, with the periods increased ten minutes each time up to a total of forty-five minutes and with the lamp at a distance of 60 cm. For the treatment of buccal lichen planus a special compressor composed of a quartz cylinder 2 cm. in diameter and 20 cm. long, curved at the distal end, is attached to the local irradiation lamp in a manner that permits rotation in all directions. In the first irradiation the tolerance of the patient is determined. The second irradiation is started by applying the end of the compressor directly to the lesion and compressing it for two minutes, this is followed by irradiation for six minutes with the end of the compressor 1 cm. from the lesion. The applications of compression and irradiation are given every other day with gradual increase up to fifteen minutes for posterior lesions and twenty minutes for anterior lesions. Lingual lesions may be irradiated longer if the throat can be protected.

*Rare Manifestation of Alimentary Anaphylaxis. A. Haritantis.—p. 119

Treatment of Diabetes by Insulin in Oil—Labbe and his associates have experimented with oily suspensions of insulin in the treatment of diabetes. In view of the fact that the injections are complicated, that it is doubtful whether the tissues can endure the penetration of the substances contained in these preparations for a lifetime, and that there is no proof that large amounts of insulin are not stored and may penetrate the circulation suddenly and provoke severe accidents, the authors think

that it is better to continue using the aqueous preparations of insulin pending further research with the only preparations

Vaccination by "Anabacteria"—Legroux applies the term "anabacteria" to a formalized autolysate obtained from macerated aqueous bacterial suspensions. With anabacteria obtained from *Bacillus mallei* and *B. pestis* he has successfully vaccinated guinea-pigs against glanders and plague, respectively. With the anabacteria of *B. mallei* he has cured glanders in guinea-pigs and has produced an antibacterial horse serum which effectively immunized donkeys against glanders.

Alimentary Anaphylaxis—Maritanti reports a case of alimentary anaphylaxis that lacked the classic clinical symptoms of anaphylaxis. The principal clinical symptoms were an intermittent daily fever, which had lasted for three months, and gross hepatic hypertrophy. A slight leukopenia after meals and a periodic, temporary erythema of the scalp were the only suggestions of a possible alimentary anaphylaxis. An albumin free diet resulted in complete apyrexia and a considerable decrease in the size of the liver in six days. The production of a typical hemoclastic crisis by administration of an albuminous meal (milk) to the fasting patient after eleven days of an albumin free diet showed that the proteopexic function of the liver was impaired, various tests could discover no other hepatic insufficiency. The sensitization to albumins was further confirmed by cutaneous reaction and tachyphylaxis. A third experiment consisted in administration of a light albuminous meal after twenty days of a vegetable diet, during which period the patient had been afebrile. This meal produced not only a hemoclastic shock but a fever, thereby definitely confirming the anaphylactic nature of the patient's fever. Desensitization was accomplished in one month by combined oral and parenteral administration of peptone solutions. The author thinks the alimentary anaphylaxis in this case was probably the cause of the symmetrical hepatomegaly as well as the fever, rather than the result of the hepatic disturbance.

Hemoclastic Crisis in Diagnosis of Hepatic Diseases

—Jacchia has observed that an injection of 2 cc. of liver extract in the median cubital vein or the gluteal muscles of patients suffering from diseases of the liver occasions a hemoclastic crisis. The author obtained sixteen positive results while experimenting with seventeen patients, and ten negative results in ten persons with normal livers. Results were negative in four tests performed with intravenous injections of 1 cc. of a mixture of chiniofon and casein. In cases giving a positive reaction, the extract brought about a definite leukopenia with diminution of the leukocytes varying from 1,000 to 4,000 cells per cubic millimeter. The leukopenia was proportionate to the quantity of extract injected. Two hours after intravenous injection, a leukocytosis developed in contrast to the leukopenia. The leukopenia was often accompanied by a relative lymphocytosis, developed at the expense of the polymorphonuclear neutrophils. This lymphocytosis diminished but did not disappear two hours after the injection. In all cases there was a slight fall of the arterial pressure but within restricted limits (between 5 and 15 mm. mercurcy), and a rise in pressure was never observed after the injection. The variations in the arterial pressure lasted two hours. In a patient with simple catarrhal jaundice, the extract occasioned a striking leukopenic reaction (diminution of 2,790 leukocytes) without lymphocytosis, and a slight drop in arterial pressure during the acute phase of the disease, during convalescence, some twenty-five days later, another injection of the same extract gave a negative result, producing a leukocytosis (increase of 1,240 leukocytes after half an hour and 1,550 after two hours) instead of a leukopenia, did not modify in any way the leukocytic formula, and only slightly increased the arterial pressure half an hour after the injection. The author found that the maximum intensity of the reaction was reached half an hour after the intravenous injection and one hour after the intramuscular injection. He believes this was caused by anaphylactic phenomena brought on by protein substances. He plans further experiments to clear up this point.

*Gastric Hemorrhages of Obscure Origin. G. Pupini—p. 31.
Malignant Renal Tumors of Infants. S. Scandurra—p. 50.

Resection of Epididymis—Alberti reviews the literature of the pathologic lesions of the epididymis with especial attention to tuberculosis of the testis and to nonspecific and fibrous epididymitis. He reports six cases with extensive resection of the head of the epididymis followed by immediate reimplantation of the vas and accurate covering up, by means of interrupted catgut sutures, of the epididymal or deferential flap with the testis and consequent reconstruction of the external layers. The clinical results were deemed entirely satisfactory.

Gastric Hemorrhages—Pupini describes a case of parenchymatous gastrorrhagia of probable inflammatory origin (hemorrhagic gastritis) of six years' duration and refers incidentally to two other patients, observed for a number of years, with nonulcerous gastric hemorrhages. The author states that the diagnosis of gastrorrhagia of nonulcerative origin due to primary lesions of the stomach and not ascribable to local or general extragastric diseases is extremely difficult and should be made only by exclusion. These hemorrhages can be caused by circumscribed lesions (aneurysms, primary but not military varicose veins), by diffuse lesions of the gastric wall (arteriosclerosis, syphilis, amyloid degeneration of the blood vessels), or by obscure etiologic alterations of the mucosa of the stomach (gastritis). The author maintains that it will always be impossible to differentiate between them clinically and that they should be called parenchymatous hemorrhages due to diffuse alterations of the wall of the stomach. The author deems it best to operate only in cases unresponsive to medical treatment. In many cases extensive gastric resections do not always give sure results, whereas gastro-enterostomy often does. The author states in conclusion that prolonged postoperative, medical, dietetic and climatic treatment (transfusions of solutions of calcium salts, high mountain climate and so on), is of palliative value.

Riforma Medica, Naples

40 77 116 (Jan. 21) 1933

*Inconveniences of Acridinic Treatment and Ungual Alteration Due to Acriflavine Hydrochloride. L. Ciarrocchi—p. 91.
Postoperative Peptic Ulcer Ending in Gastric Fistula. L. Rieppi—p. 107.

Inconveniences of Acridinic Treatment and Ungual Alteration Due to Acriflavine Hydrochloride—Ciarrocchi discusses the disturbances resulting from the intravenous injection of acridine yellow derivatives. He cites the following as immediate disturbances recorded in the literature: sensations of heat at the face, neck and genitalia, tachycardia, bradycardia, olfactory paresthesia, facial congestion, constriction at the neck, sensation of precordial weight, nausea followed by biliary and alimentary vomiting, cephalgia and vertigo. He gives as late disturbances: gastralgia, alimentary vomiting, diarrhea, primary acridinic jaundice, fever, frequent and painful micturition, acute nephritis, arthritis, yellowish cutaneous discoloration and erythema. He states that the immediate disturbances occur in most patients after the first injection of acridine and that the late manifestations occur rarely. To these he adds now a leukonychia of the thumbs found in two patients treated with an intravenous injection of 5 cc. of a 20 per cent solution of acriflavine hydrochloride. One patient, whose hands had been exposed to the sun on an average of three hours daily, developed an immediate total white discoloration of the unguis lamina, the other, who had been less exposed to the sun, developed only a partial leukonychia six weeks after the injection. The author has reviewed a large number of clinical cases treated with acridine and found that the late disturbances seldom occurred unless the patient had previous hepatic or renal alterations. He has found but one fatal case, a patient with gradual endocarditis who, six days before death, had been given an intravenous injection of 20 cc. of a 1 per cent solution of acriflavine hydrochloride. He concludes that acridine derivatives rarely cause serious dis-

turbances and are in general successfully administered in most diseases such as pneumonia, meningitis, endocarditis, streptococcal and staphylococcal septicemia, epidemic encephalitis, acute articular rheumatism, pyelonephritis and chronic urticaria

Porphyrins and Their Significance in Pathology of Digestion I Boas—p 87

Coronary Thrombosis and Diabetes—Gottsegen describes two cases in which a coronary thrombosis existed simultaneously with disturbances in the carbohydrate metabolism. He considers unjustified the opinion that in the occurrence of these two conditions diabetes is always the causal factor. Just as diabetes, which frequently is congenitally combined with arteriosclerosis, may further the development of the latter and thus cause changes in the coronary vessels, so coronary thrombosis in the presence of generalized arteriosclerosis may cause various disturbances in the sugar metabolism, from transitory glycosuria to diabetes.

Gastric Secretion During Sleep—Henning and Norpoth studied the gastric secretion of ninety-one sleeping persons, some healthy and some with gastric disturbances. They found that in healthy persons the secretory function rested completely during the entire period of nightly sleep. In a great number of patients with gastric disorders, largely duodenal ulcer, maximal secretion of gastric glands was observed, but a continuous secretion during the nightly sleep was observed also in cases of chronic hypertrophic gastritis and in some persons who, although they were free from gastric complaints, showed signs of sympathetic neurosis. In a number of these patients it was possible to demonstrate continuous gastric secretion during the nightly sleep over longer periods. The authors discuss the significance of their observations for the pathogenesis of ulcer and the pains produced by ulcer. They think that the described method is the only one that gives a true picture of the gastric secretion, because it eliminates disturbing, psychic influences.

Porphyrins in Pathology of Digestion—Boas has investigated the stercoporphyryns as well as the porphyrins found in the urine. In discussing the stercoporphyryns he gives especial attention to the diagnostic significance of deuteroporphyry. This porphyrin has a clinical diagnostic significance for those rare cases of carcinoma of the esophagus, stomach or intestine in which the stools show no peroxidase reactions. But deuteroporphyry is of greater clinical significance in ulcers of the stomach and the duodenum and in peptic jejunal ulcers. In ulcers with positive blood reactions, the disappearance of deuteroporphyry and not the cessation of the reactions indicates that the ulcer reaches the stage of cicatrization. In ulcers that give a negative blood reaction, the repeated demonstration of porphyrin indicates the presence of an uncicatrized peptic defect. A constantly negative deuteroporphyry test, provided the blood reaction is likewise negative, positive roentgenologic signs not-

withstanding, indicates a cicatrized ulcer, eventually complicated by a chronic gastritis. The deuteroporphyry test is of significance also for the therapy in that an ulcer cannot be considered cured until it gives a negative result. The author investigated the occurrence of porphyrin in the urine primarily in biliary and in hepatic disorders. He emphasizes that it is necessary to differentiate between periodic and chronic porphyrinuria. The periodic form occurs in disorders that take a cyclic course. It was observed in cholecystopathies and in hepatopathies during the period of acute inflammation, and also following severe hematemesis or melena. The author observed chronic porphyrinuria particularly in metastatic carcinoma of the liver and in carcinoma of the gallbladder, but also in untreated cases of pernicious anemia. Coproporphyrin was the form most often found in porphyrinuria, but in a few instances another form was detected, which indicates that protoporphyry may likewise occur in the urine. The author points out that methods combining simplicity and exactness are still lacking for the determination of porphyrins in the feces and in the urine. He realizes that for the stercoporphyryns this will hardly be possible, but he thinks that efforts should be made to improve the methods for the determination of porphyrins in the urine.

Pain in Angina Pectoris—Following introductory remarks about former theories on the pathogenesis of pain in angina pectoris, Dietrich and Schwiegk relate their own observations, particularly their electrocardiographic studies during oxygen deficiency. These revealed that want of oxygen produces changes in the electrocardiogram of healthy persons, and that similar but more pronounced electrocardiographic changes were noted in patients who are subject to attacks of angina pectoris. Development of pains similar to those of a spontaneous attack was also observed during oxygen deficiency of patients subject to angina pectoris. The authors think that during an attack of angina pectoris there exists an ischemia of the cardiac muscle and that not only the changes in the electrocardiogram but also the pains are a result of this ischemia. They consider it improbable that in addition to the oxygen deficiency there also exists a spasm of the coronary arteries, because as long as anoxemia persists it is impossible to counteract the pain by administration of glyceryl trimtrate. The authors hope that their method of deficient oxygen respiration will help also in differentiating various forms of angina pectoris, which would be important not only for the prognosis but also for the therapy.

Quantitative Determination of Porphyrin in Urine—Schreus and Carrie, after evaluating three other methods for the determination of porphyrin in the urine, namely, weighing, the fluorescence method and the colorimetric method, describe their experiences with the spectrophotometric method. The quantitative determination of porphyrin by means of the spectroscopic method is based on the observation that the intensity of the absorption band of porphyrin solutions is proportional to their porphyrin content. Thus, if the absorption band of solutions of known porphyrin content is compared in the spectroscopic with that of solutions of unknown content, the porphyrin content of the latter can be readily detected. After a short review of the technique, which has been described in a previous publication (*Klin Wchschr* 10 1017 [May 30] 1931), the authors discuss sources of error that may develop in the separation of coproporphyrin. Then they discuss the application of the method in the determination of uroporphyrin, and certain technical points that may be helpful in some instances. They emphasize that the spectrophotometric determination of porphyrin fulfills all the requirements of a clinical quantitative method of demonstration.

Sodium Salt of Barbituric Acid Derivative as New Anesthetic—Ernst points out that, although the methods of general anesthesia applicable in clinics and hospitals have been greatly improved in recent years, the physician in general practice, particularly in emergency surgery, was still at a disadvantage. Recently a sodium salt of a barbituric acid derivative has been prepared and found to produce a satisfactory short general anesthesia. Tests revealed that the intravenous injection of 10 cc of a 10 per cent aqueous solution of the sodium salt is the best method of application. The injection should be made slowly and cautiously. The author advises injecting the first 4 cc within the first minute, and then taking from eight to ten seconds for each additional cubic centimeter. The injection is entirely painless. The duration of the anesthesia varies in different persons and according to the quantity of anesthetic injected. The average length is from fifteen to twenty minutes, but occasionally longer. This period, during which the reflexes are abolished, is followed by a quiet but shallow sleep of variable length. Self observations of several physicians, who had experienced several types of anesthesia, were to the effect that this anesthetic is more pleasant to take than any other. The harmlessness of this method of anesthesia is proved by the fact that there occurred not a single serious complication in 250 administrations. Secondary effects were observed only in a few instances: headaches twice, nausea three times, diplopia once and excitability twice. These slight disadvantages are more than compensated by the advantages. The fact that this anesthetic exerts little influence on circulation and respiration makes its use advisable in old persons and in those with impaired cardiac action. In diseases of the respiratory passages its use is less dangerous than that of the usual inhalation anesthetics or tribrom-ethanol. Diseases of the liver and of the kidney are no contraindication to the use of the sodium salt of the barbituric acid derivative, and the possibility of repeated application is another advantage of the preparation. The author employed the new method of anesthesia most frequently in pyogenic infections, phlegmons, abscesses, opening of pleural empyemas, and various other surgical interventions in which local anesthesia is less satisfactory, such as in reposition of dislocations and fractures of the joints.

Renal Insufficiency Produced by Retention of Urine—In discussing the causal factors of urinary retention, Rubritius calls attention to studies made by Fuchs which revealed that complete evacuation of the bladder is accompanied by a contraction of the upper urinary passages, whereas gradual filling of the bladder results in a dilatation of the upper urinary

passages. This author was able to show also that the condition was not due to mechanical stasis but rather to a reflex action. This reflex is evidently produced by dilatation and burdening of the vesical fundus. Elimination urography in patients with hypertrophy of the prostate convinced Rubritius that in the beginning stages of prostatic hypertrophy the contraction and dilatation of the ureters is promptly elicitable, whereas in patients with retention of urine the upper urinary passages show nearly always a dilatation, that is, the dilated condition has become more or less fixed. Moreover, this dilatation is accompanied by an hypertrophy of the ureteral musculature. The author discusses the effect of these changes in the upper urinary passages on the renal parenchyma, and the second causal factor of urinary retention, namely, the vesico-ureteral reflux. It is important whether the vesico-ureteral reflux takes place while the urine is clear, that is, in a patient without infection, or in a patient in whom infection is present. If infection exists, reflux may lead to a serious infection of the renal parenchyma. The author shows that operative treatment of prostatic hypertrophy has a prospect of success only if an existing renal insufficiency, no matter whether it is caused by retention or by infection, can be brought to regress. Since the symptoms of renal insufficiency are usually too slight to permit a diagnosis, the author recommends the water and concentration test and the determination of the rest nitrogen and of the indican content of the blood serum to determine the condition of the renal function. He considers the water and concentration test particularly valuable. The main factor in overcoming renal insufficiency is to do away with the stasis. In mild cases this is best done by the retention catheter, and in severe cases by a suprapubic fistula. The author shows that age is no contraindication to operative treatment and maintains that a prostatectomy under local anesthesia is well tolerated by octogenarians. It is essential for the success of an operative intervention that it be performed before a serious renal insufficiency has developed.

Chemical Diagnosis of Malignant Tumors—Fuchs and Devrient call attention again (see abstracts in THE JOURNAL, Dec 3, 1932, p 1990, and Dec 31, 1932, p 2300) to the cancer reaction devised by Fuchs several years ago. They emphasize that with this method it is possible to detect the presence of malignant tumors or of certain infectious diseases, and that the test also reveals the relationship between the aggressiveness of the disease and the defense power of the organism.

Action of Parathyroid Extract on Ulcer of Leg and on Alveolar Pyorrhea—Sucher states that the favorable effects of parathyroid hormone in angioneurotic conditions induced her to continue her experiments in this direction and to try it in the treatment of persistent ulcers of the leg. By means of a syringe, 1 cc of parathyroid extract, otherwise used for injection, is dropped on the ulcer and the ulceration is covered with dry sterile gauze. The extract is applied three times each week or every day. This external application is combined with internal administration of a calcium preparation. The result of the application of the parathyroid extract is that a torpid ulcer becomes hyperemic, granulation sets in, and finally complete cure is effected. Local application of the parathyroid extract was also tried in alveolar pyorrhea. The result was that the inflammatory manifestations and pains disappeared, but the looseness of the teeth was not influenced.

Rectal Diathermy in Gynecologic Disorders—According to von Bodo, diathermy is the most effective of the physical methods employed in the treatment of disorders of the female genitalia. Of the three methods of application, percutaneous, vaginal and rectal, the vaginal method is the one that is most frequently employed. However, the author maintains that in certain inflammatory processes of the small pelvis, particularly in inflammation, contraction and rigidity of the sacro-uterine ligaments, the rectal method of application is superior. He found the olive electrode of Kelen to be best suited for rectal diathermy. Rectal application has to be done with great care, because the nearness of the sacrum increases the danger of burning. The increase in heat should be gradual to a maximum of not more than 15 amperes. The application lasts from twenty to thirty minutes. The author employed the abdominodorsorectal diathermy in 120 cases. There was posterior parametritis in thirty-five of these cases, retrofixation of the uterus in twenty-five, salpingo-oophoritis in twenty-four, tumor of the

adnexa with posterior parametritis in sixteen, and parametritis of the right or left side and posterior parametritis in twenty. The result was that cure or complete restitution was obtained in 47 per cent of the patients, improvement was noticeable in 45 per cent, and the treatment was entirely ineffective in only 8 per cent. In the course of two years, 12 per cent of the patients had relapses. The author further gives his theory of the mechanism of the diathermy treatment.

Notched Auricular Wave—Spehr states that in 4,000 electrocardiographic investigations on persons with and without circulatory disturbances he observed 180 cases with notching of the auricular wave. Continuous tests revealed that the symptom may be constant or periodic. It was found seventeen times in patients without circulatory disorders, but all these patients had a sympathetic neurosis. As a rule, notching of the P wave was found in patients with circulatory disorders. But the circulatory condition is not an important factor, for most of these patients showed a well compensated circulation. A slight increase in incidence was noted in insufficiency of the left with good functioning of the right heart. In the majority of cases that came up for postmortem examination a myocardial impairment of the auricles could be noted, but in some instances macroscopic examination revealed no anomalies. On the other hand, it is known that numerous cases of myocarditis of the auricles do not show notching of the auricular wave. Consequently the author assumes that the notched wave becomes manifest only if certain channels of the auricles are impaired by organic or functional disturbances. The author does not consider the notched auricular wave merely a variation within the sphere of normality as has been done by others. The organic causes of the notched P wave can be differentiated into degenerative and inflammatory myocardial changes. In the degenerative forms primarily coronary sclerosis and chronic disorders of the cardiac muscle, repeated examination revealed notching to be a constant anomaly. In acute inflammatory myocarditis that nearly always concurs with infections and particularly rheumatic diseases, the notched P wave is an early symptom of myocarditis but it usually disappears again. Cases of rheumatic myocarditis and endocarditis, in which the notching of the P wave does not disappear or even increases after the acute manifestations have subsided have an unfavorable prognosis. It was observed repeatedly that the increase in notching was accompanied by a decompensation in the form of neutralization. The notching of the P wave is also frequently noted before the development of absolute arrhythmia. The author considers the occurrence of notching of the P wave during sympathetic neurosis the result of a disturbance in the innervation of the heart which in turn affects the conduction system or the blood supply of the heart for as a rule these patients also have bradycardia and prolonged conduction time.

Gastritis and Genesis of Gastric Ulcer—Meyer shows that the term gastritis is often used in a rather vague manner and he advises that the diagnosis of gastritis should be based only on definite signs. As such he considers the leukocyte con-

tent of the secretion of the fasting stomach and the bacteriologic observations on the gastric and duodenal juices. Acute gastritis and fermentation dyspepsia can be produced by relative insufficiency of the digestive organs, but the infectious factor seems to be of greater significance. An important cause of chronic gastritis is *Monilia albicans*, and peptic ulcer that frequently develops from chronic gastritis is an infection of the wall of the stomach with *Monilia albicans*. The author discusses the significance of fungi, particularly yeasts, for enteritis and he gives several case reports to illustrate this.

Biglandular Endocrine Disease with Aspects of Addison's Disease—Klingner describes the clinical history of a patient who for three weeks showed the symptoms of acute Addison's disease and then, within a few days, died of severe meningitis with encephalomyelitic manifestations. The necropsy revealed that the patient had had a biglandular endocrine disorder of the thyrosuprenal type. The changes in Addison's disease and have been designated "cytotoxic contracted suprarenals" with primary destruction of the cortex. The author is inclined to consider that the more or less analogous changes in the thyroid likewise are cytotoxic. He believes that the disease is caused by toxic factors the nature of which is not yet understood. The described case may corroborate the opinion of some authors, who assume that constitutional factors play a part in the pathogenesis of such conditions. The anatomic changes may have existed several years previous to the acute manifestation. The terminal meningitic encephalomyelitic manifestations are most likely of toxic origin, since an anatomic cause was not found. An intercurrent mild form of otitis media evidently was sufficient to produce the severe manifestations that resulted in death. The predominant destruction of the suprarenal cortex with comparatively well preserved medulla may explain the absence of a reduction in the blood sugar content, and the same factor may be responsible for the absent or only slightly developed atypical pigmentation. The nitrogen rest was increased over 100 per cent, but the kidneys revealed no changes that could be considered the cause of this. On the basis of investigations conducted by others the author thinks it possible that the suprarenal cortex influences the nitrogen elimination. The involvement of the thyroid was not indicated by clinical manifestations, and cases of this nature that have been reported before likewise presented the aspects of Addison's disease and showed no symptoms indicative of a myxedema. This explains why there are no records of tests of the basal metabolism or of the iodine content of the blood. The majority of cases that have been reported so far were in women of the menopausal age.

Patients with Inoperable Cancer of Prostate Gland—Obstruction to voluntary urination can be relieved by establishing a suprapubic bladder fistula. Invasion of the rectum with attending painful tenesmus and partial or complete obstruction of the intestine is treated by establishment of an artificial anus or by sectioning the end of the intestine and dividing the sphincter. Early and severe pains are characteristic of prostatic carcinoma. In the advanced inoperable cases the pain is frequently agonizing and unremitting. Kirschner feels that these unfortunates should be given the benefit of the latest advances in the control of unremitting pain. For this purpose three methods are available. 1 Chordotomy may be employed. The author sections the anterolateral columns of the spinal cord on both sides at the level of the fourth thoracic vertebra. The employment of his so-called high pressure local anesthesia method, together with the use of the electric knife, reduces the bleeding attendant on laminectomy to a minimum. To avoid

Patients with Inoperable Cancer of Prostate Gland—Obstruction to voluntary urination can be relieved by establishing a suprapubic bladder fistula. Invasion of the rectum with attending painful tenesmus and partial or complete obstruction of the intestine is treated by establishment of an artificial anus or by sectioning the end of the intestine and dividing the sphincter. Early and severe pains are characteristic of prostatic carcinoma. In the advanced inoperable cases the pain is frequently agonizing and unremitting. Kirschner feels that these unfortunates should be given the benefit of the latest advances in the control of unremitting pain. For this purpose three methods are available. 1 Chordotomy may be employed. The author sections the anterolateral columns of the spinal cord on both sides at the level of the fourth thoracic vertebra. The employment of his so-called high pressure local anesthesia method together with the use of the electric knife, reduces the bleeding attendant on laminectomy to a minimum. To avoid

pain from the posterior roots, the latter may be injected with a solution of 2 per cent procaine hydrochloride. He was able by this method to afford complete relief to a patient with intractable pain and rectal tenesmus. 2 For patients too weak to undergo a chordotomy, the method of "continued spinal anesthesia" may be employed. With the author's method of "delimited zonal spinal anesthesia," 2 or 3 cc of a 70 per cent alcohol solution is injected into the dural sac. This method is particularly applicable in cases of pelvic carcinoma of the prostate gland, the rectum, or the female genitalia. Two patients treated by this method were completely relieved of pain. 3 The same result may be obtained by epidural injection of alcohol through the sacral hiatus.

Restoration of Renal Function—Walters states that the return of renal function after removal of obstructing lesions seems remarkable. Evidence of this is the rapidity with which a distended pelvis will return to within normal limits of size and capacity, and with which renal function improves after complete removal of such obstructions. If one is to attempt to preserve a kidney injured as the result of an obstructing lesion when the opposite kidney is normal, one must have sufficient evidence that such a kidney will return to reasonable function after relief of the obstruction and after control of the infection, rather than to decrease in function and to atrophy. A most important point in such a decision is the remaining amount of renal parenchyma, as measured by the thickness of the cortex and the size of the calices. Even in cases in which a good deal of infection appears to coexist with the obstructing lesion, even in the presence of small cortical abscesses, the kidney may free itself of such infection after relief of the urinary obstruction. In such cases, removal of the fibrous capsule of the kidney, enabling the cortical infection to discharge itself, should be a part of the procedure. In the presence of stones in the kidney and ureter, tests of renal function, such as excretion of phenolsulphonphthalein, indigo carmine and various mediums used in intravenous urography, do not give an accurate index of renal function. Such being the case, whenever sufficient renal parenchyma remains the kidney should not be removed until evidence accumulates after removal of the obstruction that the kidney is not functioning. Indications for conservative procedures, such as resection of the renal pelvis, reimplantation of the ureter or removal of obstructions due to peripelvic tissue, are most strikingly indicated when the hydronephrosis is bilateral or if unilateral when sufficient renal parenchyma remains to justify its preservation. In making the decision as to the best conservative treatment to follow in hydronephrosis, the guide is one's own experience, it being remembered that the safest and best procedure is the one that produces adequate and complete relief of the obstruction, with only disturbance of the renal pelvis or ureteral tissue.

Cause of Napoleon's Death—Kalma states that the general view held among historians and medical men is that Napoleon died of cancer of the stomach. This view is based on the postmortem examination, which showed that the emperor's stomach was the seat of widespread "scirrhous" ulcerations. To the medical reader of today a critical examination of the clinical course of the illness conveys the picture of a gastric ulcer with periodic dyspeptic symptoms, prolonged remissions, increasing anemia (as a result of occult hemorrhage), irritability of the stomach with daily frequent vomiting, severe attacks of pain, and recurring hemorrhage of the stomach. If one adheres to the necropsy diagnosis one faces an insurmountable contradiction between the latter and the clinical picture. A critical examination of the postmortem report shows beyond doubt, however, that the antral part of the emperor's

stomach was the seat of a characteristic, funnel-shaped callous ulcer, passing obliquely through the stomach wall, and the floor of which was firmly adherent to the lower surface of the liver. This observation is mentioned casually in the postmortem report, while chief attention is directed to the numerous ulcerations spread over almost the whole of the mucous membrane of the stomach. These ulcerations were looked on as cancerous or as ulcerations in the stage of cancerous degeneration. The clinical picture is definitely against the view that the ulcerations in question were of cancerous nature. In such a case the stomach would have been transformed into a stiff tube without any contractile power. Moreover, no metastases were found at necropsy. On the other hand, by assuming that Napoleon's stomach was the seat of a simple widespread ulcerous gastritis, the anatomic observations can be brought into complete harmony with the clinical picture. This hypothesis finds support in the anatomic investigations of recent years concerning the "gastric" pathogenesis of peptic ulcer. It should be pointed out that ulcer disease was unknown in practical medicine during Napoleon's time. It was through Cruveilhier's investigation, unanimously accepted by medical research of more recent times, that gastric ulcer became a separate clinical entity differentiated from cancer of the stomach.

Prostatic Hypertrophy—On the basis of histologic studies of normal and hypertrophic prostate glands, Krogius arrives at the following conclusions as to the nature and development of prostatic hypertrophy. The process is not one of tumor formation. It is to be regarded as a hyperplastic regenerative process aiming at the formation of new gland parenchyma to replace that used up in an elderly man, analogous to the regenerative phenomena observed in the prostate under normal conditions. Like the normal regenerative phenomena, the exuberant process leading to prostatic hypertrophy begins in the glandular ducts the epithelium of which retains its ability to form new gland parenchyma until advanced age. Prostatic hypertrophy derives its particular significance from the fact that the hyperplastic process takes place mainly in the middle part of the prostate, developing a steady proliferation of the peritubular connective tissue in the abundant fibromuscular stroma of this region apparently because the young glandular buds require a loose stroma for their growth. In this way there develop small "adenofibromas," which subsequently expand in size and give rise to the localized nodular formations so characteristic of prostatic hypertrophy. The so-called glandless nodules also take their origin from the peritubular layer of connective tissue. The epithelial covering of the newly formed glandular buds soon develops into a mature, secreting epithelium of the apocrine type, which delivers an apparently normal prostate secretion. However, the growth of the nodules results in a compression of the efferent ducts, with the result that in a more advanced stage of the disease the excretory function of the prostate scarcely derives any further benefit from the secretion of the nodules. At the same time, distinct retrogressive changes set in with dilatation and cyst formation. The histologic structure and the entire mode of development of prostatic hypertrophy closely resemble cystic mastopathy.

Essential Hematuria—Löfberg emphasizes the uncertainty in the diagnosis of so-called essential hematuria as well as the difficulties in selecting the proper surgical procedure. Essential or idiopathic hematuria is characterized by profuse hemorrhages coming from one side in the absence of any recognizable macroscopic lesion. The author points out, however, that even the inspection of a split kidney is not necessarily conclusive, because pathologic changes may be revealed on microscopic examination. Naunyn stated that nephritis was the underlying cause in most cases, though he admitted that a normal kidney may bleed. The author reviews the various theories as to the cause and reports the eight cases observed in the course of ten years at the General Hospital in Malmö (Sweden). A nephrectomy was performed in seven. Interstitial inflammatory changes, believed to be the common cause of essential hematuria, were present in only one case. Thrombosis and embolism were noted in one, and in one case pyelitis granulosa was present. In four cases there were no changes in the parenchyma. Therapeutic indications are vague. Operative intervention is frequently of exploratory nature. Of the various operative procedures, nephrectomy best meets the indications. All of the author's patients were restored to health.
